This skeleton presents itself in three principal textures, the fibrous, chalky, and glassy. In a few cases it is gelatinous. (See *Fibrospongiae*, *Calcispongiae*, *Silicespongiae*, *Mucospongiae*.) A nearly constant and very characteristic feature of sponge-skeletons is the presence of calcareous or silicious spicules. (See *spicule*.) Spicules in excess of fibrous tissue, and especially when consolidated in a kind of network, form the glass-sponges, some forms of which are very beautiful. (See cut under *Euplectella*.) fishes the whole skeleton is cartilaginous. In most vertebrates, however, the cartilage forming the skeleton of the embryo or fetus is mainly converted into bone by the process of ossification, or deposition of bone-earth, some parts, especially of the ribs, remaining as a rule cartilaginous. The vertebrate endoskeleton consists of axial parts, the *axial skeleton*, in a series of consecutive segments, the vertebrae, with their immediate offshoots, as ribs, and at the head end a skull or cranium (except in the *Acerania* or lowest fishes); and of appendages, the *appendicular skeleton*, represented by the one or two (never more) pairs of limbs, if any, including the pectoral and pelvic arch, or shoulder- and hip-girdle, by means of which the limbs are attached to the axis or trunk. Various other ossifications may be and usually are developed in

picture as far as they were capable; after which he re-touched the whole himself.

Spring, Jump, Vault. *Skipping* is more than tripping and
less than leaping, bounding, springing, or jumping; like
tripping, it implies lightness of spirits or joy. It is about
equal to hopping, but hopping is rather heavy and gen-
erally upon one foot or with the feet together, while *skip-
ping* uses the feet separately or one after the other. A
hop is shorter than a *jump*, and a *jump* than a *leap*: as, the
hop of a toad; the *jump* of a frog; the *leap* of a marsh-frog;
a *jump* from a fence; a *leap* from a second-story window.
Skip, trip, bound, and spring imply elasticity; *bound,*
spring, leap, and vault imply vigorous activity. *Vault* im-
plies that one has something on which to rest one or both
hands; *vaulting* is either upon or over something, as a
horse, a fence, and therefore is largely an upward move-
ment; the other movements may be chiefly horizontal.

sons so placed as to give it a large radius of revolution.

skunk early attracted attention. It is mentioned in 1636 by Sagard-Théodat by several terms based on its Indian names, as *scangaresse*, *ouinsque*, etc., and in the same passage, in his "History of Canada," this author calls it in French "*enfant du diable*," a name long afterward quoted as specific. It is the *fiskatta* of Kalm's "Travels," commonly translated *polecat*, a name, however, common to various other ill-scented *Mustelidae*. (See def. 2.) *Chinche*, *chín-ga*, and *moufette* (specifically *moufette d'Amérique*) are book-names which have not been Englished. The New Latin synonyms are numerous. The animal inhabits all of temperate North America, and continues abundant in the most thickly settled regions. It is about as large as a house-cat, but stouter-bodied, with shorter limbs, and very long bushy tail, habitually erected or turned over the back. The color is black or blackish, conspicuously but to a variable extent set off with pure white—generally as a frontal stripe, a large crown-spot, a pair of broad divergent bands along the sides of the back, and white hairs mixed with the black ones of the tail. The fur is valuable, and when dressed is known as *Alaska sable*; the blackest pelts bring the best price. The flesh is edible, when prepared with sufficient care. The skunk is carnivorous, like other members of the same family, with which its habits in general agree; it is very prolific, bringing forth six or eight young in burrows. The fluid which furnishes the skunk's almost sole means of defense was long supposed and is still vulgarly believed to be urine. It is the peculiar secretion of a pair of perineal glands (first dissected by Jeffries Wyman in 1844), similar to those of other *Mustelidae*, but very highly developed, with strong muscular walls, capacious reservoir, and copious golden-yellow secretion, of most

slang³ (slang), *n.* [Of obscure cant origin; the form suggests a connection with *sling*, in a way indicated by the use of *sling* and *fling* in 'to sling epithets,' 'to fling reproaches,' etc., and by similar uses of related Scand. forms, as Norw. *sleng*, a slinging, a device, a burden of a song; *slengja*, sling (*slengja kjeften*, abuse, lit. 'sling the jaw'); *slengjenamn*, a nickname; *slengje-ord*, an insulting word or allusion; *leel. slyngur*, *slyngum*, cunning: see *sling¹*. The noun, in this view, must have arisen in quasi-composition (*slung*-patter, *slang*-word, *slang*-name, etc.), or else from the verb. Evidence of early use is lacking. The word has nothing to do with *language* or *lingo*, and there is no evidence to establish a Gipsy origin.] 1. The cant words or jargon used by thieves, peddlers, beggars, and the vagabond classes generally; cant.

Slang in the sense of the cant language of thieves appears in print certainly as early as the middle of the last century. It was included by Grose in his "Dictionary of the Vulgar Tongue," published in 1785. But it was many years before it was allowed a place in any vocabulary of our speech that confined itself to the language of good speakers and writers. Its absence from such works would not necessarily imply that it had not been in frequent use. Still, that this never had been the case we have direct evidence. Scott, in his novel of "Redgauntlet," which appeared in 1824, when using the word, felt the necessity of defining it; and his definition shows not only that it was generally unknown, but that it had not then begun to depart at all from its original sense. In the thirteenth chapter of that work, one of the characters is represented as trying to overhear a conversation, . . . but . . . "what did actually reach his ears was disguised so completely by the use of cant words and the thieves' Latin called *slang* that, even when he caught the words, he found himself as far as ever from the sense of their conversation." No one who is now accustomed either to speak slang (in def. 2), or to speak of the users of it, would think of connecting it with anything peculiar to the language of thieves. Yet it is clear from this one quotation that the complete change of meaning which the term has undergone has taken place within a good deal less than sixty years. *The Nation*, Oct. 9, 1890, p. 289.

Let proper nurses be assigned, to take care of these babes of grace [young thieves]. . . The master who teaches them should be a man well versed in the cant language commonly called the *slang* patter, in which they should by all means excel. *Jonathan Wild's Advice to his Successor* (1758). (*Hotten*).

2. In present use, colloquial words and phrases which have originated in the cant or rude speech of the vagabond or unlettered classes, or, belonging in form to standard speech, have acquired or have had given them restricted, capricious, or extravagantly metaphorical meanings, and are regarded as vulgar or inelegant. Examples of slang are *rum* for 'queer,' *gay* for 'dissolute,' *corned*, *tight*, *slued*, etc., for 'intoxicated,' *awfully* for 'exceedingly,' *jolly* for 'surprising, uncommon,' *daisy* for 'something or somebody that is charming or admirable,' *kick the bucket* or *hop the twig* for 'die,' etc. This colloquial slang also contains many words derived from thieves' cant, such as *pal* for 'partner, companion,' *cope* for 'fellow,' and *ticker* for 'watch.' There is a slang attached to

certain professions, occupations, and classes of society, such as racing *slang*, college *slang*, club *slang*, literary *slang*, political *slang*. (See *cant*.) Slang enters more or less into all colloquial speech and into inferior popular literature, as novels, newspapers, political addresses, and is apt to break out even in more serious writings. Slang as such is not necessarily vulgar or ungrammatical; indeed, it is generally correct in idiomatic form, and though frequently censured on this ground, it often, in fact, owes its doubtful character to other causes. *Slang* is often used adjectively: as, a *slang* expression. See the quotations below.

The smallest urchin whose tongue could tang Shock'd the dame with a volley of *slang*. *Hood*, Tale of a Trumpet.

Cant, as used in the phrases "thieves' cant," "tinkers' cant," "printers' cant," or the cant of any craft or calling, is really a language within a language, and is intended to conceal the thoughts of those who utter it from the uninitiated. *Slang*, on the other hand, is open to all the world to use, and its ranks are recruited in various ways. *N. and Q.*, 7th ser., VII. 341.

Center slang, thieves' slang in which the middle vowel of a word is taken as its initial letter, and other letters or syllables are added to give the word a finish, as *lock* becomes "ockler," *pitch*, "itchper," etc. *Ribton-Turner*, Vagrants and Vagrancy, p. 478.—**Riming slang**, a kind of cant or secret slang spoken by street vagabonds in London, consisting of the substitution of words or sentences which rhyme with other words or sentences intended to be kept secret: as, "apples and pears" for *stairs*; "Cain and Abel" for *a table*. 3. A rock the most striking characteristic of which is its fissile structure, or capability of being easily split or cleft into thin plates of nearly uniform thickness and smooth surfaces. The rocks in which a fissile structure is particularly well developed are almost exclusively the argillaceous, and those which have been more or less metamorphosed, and this fissility appears to be the result of the rearrangement of the particles of the rock into new combinations flattened into thin scales which lie in a direction at right angles to the direction in which the rock was pressed at the time the metamorphism was taking place. The best-known variety of slate is the common roofing-slate, which is compact, homogeneous, and fissile enough to be used for covering roofs, or for manufacture into tables, chimney-pieces, writing-slates, etc. The valuable varieties of roofing-slate come almost exclusively from the older metamorphic rocks. (See *cleavage* and *foliation*.) North Wales is by far the most important slate-producing region of the world, some beds having been worked there as early as the twelfth century. The principal quarries are in southern Carnarvonshire and Merionethshire in the Lower Silurian, and in Montgomeryshire in the Upper Silurian. There are also quarries in Cornwall in the Devonian, and slates of the same geological age are obtained in France in considerable quantity, as well as in parts of Germany adjacent to the Rhine. There are various quarries in Devonshire in the Carboniferous; but in most of them the slate furnished is not of first-rate quality; and, in general, it may be said that the Carboniferous is the highest geological formation producing what can properly be denominated *slate*. The slate of the United States comes almost entirely from a very low position in the geological series, as is also the case in Europe. Pennsylvania and Vermont are the principal slate-producing States, and they together furnished in 1889 nearly six sevenths in value of the total production of the country; but Pennsylvania's share was three times as great as that of Vermont.

2. The keeping or holding of slaves; the practice of keeping human beings in a state of servitude or bondage. Slavery seems to have existed everywhere from very early times. It is recognized in the Old Testament as a prevailing custom, and the Levitical laws contain many regulations in regard to slaves and their rights and duties. Serfdom died out gradually in England in the latter part of the middle ages, and slavery was abolished throughout the British empire in 1833, after long agitation, the sum of twenty million pounds sterling being paid as compensation to the slave-owners. Negro slavery was introduced into the present territory of the United States in 1620, and became recognized as an institution. The Northern States gradually got rid of their slaves by emancipation or transportation in the latter part of the eighteenth and the early part of the nineteenth century. Slavery became a leading and agitating question from the time of the Missouri Compromise (1820), and the number of slave States increased to fifteen. (See *slave State*, under *slave*², *a.*) President Lincoln, by his Emancipation Proclamation of January 1st, 1863, declared free all slaves in that part of the Union designated as in rebellion; and the thirteenth amendment to the Constitution, 1865, abolished slavery within the United States. Slavery has been abolished by various other countries in the nineteenth century, as by Brazil in 1888.

In the progress of humane and Christian principles, and of correct views of human rights, *slavery* has come to be regarded as an unjust and cruel degradation of man made in the image of God. Woolsey, Intro. to Inter. Law, § 138.

4. A South American tardigrade edentate mammal of the family *Bradypodidæ*: so called from their slow and apparently awkward or clumsy movements. The slowness of their motions on the ground is the necessary consequence of their disproportioned structure, and particularly of the fact that the feet exhibit a conformation resembling that of clubfoot in man—a disposition of the carpal and tarsal joints highly useful in climbing. Sloths live on trees, and never remove from one until they have stripped it of every leaf. They are helpless when on the ground, and seem at home only on trees, suspended beneath the branches, along which they are sometimes observed to travel from tree to tree with considerable celerity. The female produces a single young one at a birth, which she carries about with her until it is able to climb. Sloths are confined to the wooded regions of tropical America, extending northward into Mexico. At least 12 species are described, but the true number is fewer. All have three toes on the hind feet, but some have only two on the fore feet, whence the obvious distinction of *three-toed* and *two-toed* sloths (a distinction even more strongly marked in the anatomy of these animals) warranted a division of the family into *bradypodids* (*Bradypodinae*) and *choloipodines* (*Choloipodinae*). Most sloths belong to the former group, and these have the general name *ai*. The best-known of these is the collared three-toed sloth, *Bradypus tridactylus* or *torquatus*, with a sort of mane. The unan or two-toed sloth, *Choloipus didactylus*, inhabits Brazil; it is entirely covered with long coarse woolly hair. (See cut under *Choloipus*.) A second and quite distinct species of this genus, *C. hoffmanni*, inhabits Central America. (See *Tardigrada*, 1.) The name is apparently a translation of the Portuguese word *preguiça* (Latin *pigritia*), slowness, slothfulness. See the quotation.

Here [in Brazil] is a Beast so slow in motion that in fifteen days he cannot go further than a man can throw a stone; whence the Portugals call it *Pigritia*.

smell (*smel*), *n.* [*cf.* ME. *smel*, *smil*, *smul*, *sméal*, *sméal* (not found in AS.); see the verb.] 1. The faculty of perceiving by the nose; sense-perception through the olfactory nerves; the olfactory faculty or function; the physiological process or function whereby certain odoriferous qualities of bodies, as scent or effluvium, are perceived and recognized through sensation; olfaction; scent; often with the definite article, as one of the special senses; as, the *smell* in dogs is keen. The essential organ of smell is located in a special part or lobe of the brain, the rhinencephalon, or olfactory lobe, whence are given off more or fewer olfactory nerves, which pass out of the cranial cavity into the nasal organ, or nose, in the mucous or Schneiderian membrane of the interior of which they ramify, so that air laden with odoriferous particles can affect the nerves when it is drawn into or through the nasal passages. In man the sense of smell is very feeble and imperfect in comparison with that of many animals, especially of the carnivores, which pursue their prey by scent, and ruminants, which escape their enemies by the same means. Smell in the lower animals seems to be the guiding sense in determining their choice of food.

Memory, imagination, old sentiments and associations, are more readily reached through the sense of smell than by almost any other channel. *O. W. Holmes*, *Autocrat*, iv.

Smell is a sensation excited by the contact with the olfactory region of certain substances, usually in a gaseous condition and necessarily in a state of fine subdivision. *Encyc. Brit.*, XXII. 165.

3. A faint impression; a subtle suggestion; a hint; a trace; as, the poem has a *smell* of the woods.—4. An act of smelling; as, he took a *smell* at the bottle.—**Syn.** *Smell*, *Scent*, *Odor*, *Savor*, *Perfume*, *Fragrance*, *Aroma*, *Stench*, *Stink*. *Smell* and *scent* express the physical sense, the exercise of the sense, and the thing which appeals to the sense. The others have only the last of these three meanings. Of the nine words the first four may express that which is pleasant or unpleasant, the next three only that which is pleasant; the last two only that which is very unpleasant. *Smell* is the general word; the others are species under it. *Scent* is the smell that proceeds naturally from something that has life; as, the *scent* of game; the *scent* of the tea-rose. *Odor* is little more than a Latin substitute for *smell*; as, the *odor* of musk, of decaying vegetation; it may be a dainty word, as *smell* cannot be. *Savor* is a distinctive smell, suggesting taste or flavor, proceeding especially from some article of food; as, the *savor* of garlic. *Perfume* is generally a strong or rich but agreeable smell. *Fragrance* is best used to express fresh, delicate, and delicious odors, especially such as emanate from living things; as, the *fragrance* of the violet, of new-mown hay, of the breath of an infant. *Aroma* should be restricted to a somewhat spicy smell; as, the *aroma* of roasted coffee, or of the musk-rose. *Stench* and *stink* are historically the same word, in different de-

grees of strength, representing a strong, penetrating, and disgusting odor; *stink* is not for polite use.

Connection with *melt* is doubtful.] **I. trans.** To fuse; melt; specifically, to treat (ore) in the large way, and chiefly in a furnace or by the aid of heat, for the purpose of separating the contained metal. Metallurgical operations carried on in the moist way, as the amalgamation of gold and silver ores in pans, treatment by lixiviation, etc., are not generally designated by the term *smelling*. Edibilism where this is done are more commonly called mills or reduction-works, and those in which iron is smelted are usually designated as blast-furnaces or iron-furnaces. The vari-

ous smelting operations differ greatly from each other according to the nature of the combinations operated on. Simple ores, like galena, require only a very simple series of operations, which are essentially continuous in one and the same furnace; more complicated combinations, like the mixtures of various cupiferous ores smelted at Swansea by the English method, require several successive operations, entirely disconnected from each other, and performed in different furnaces. In the most general way, the essential order of succession of the various processes by which the sulphureted ores (and most ores are sulphurets) are treated is as follows: (1) calcination or roasting, to oxidize and get rid (as far as possible) of the sulphur; (2) reduction of the metal contained in the oxidized combinations obtained; (3) refining, or getting rid of the last traces of deleterious metals associated in the ores with the useful metal, to obtain which is the essential object of the operation.

II. intrins. To fuse; melt; dissolve.

Having too much water, many corns will *smelt*, or have their pulp turned into a substance like thick cream.

Mortimer, Husbandry.

smelt² (smelt), *n.* [*< ME. smelt, < AS. smelt = Norw. smelta = Dan. smelt, a smelt (applied to various small fishes); perhaps so called because it was 'smooth': cf. The common European smelt is the sparring, *O. eperlanus*; it becomes about 10 to 12 inches long, and is of an olive-green above and a silvery white below, with a silver longitudinal lateral band. It exhales when fresh a peculiar scent suggesting the cucumber. This fish is prized as a delicacy. The corresponding American smelt is *O. mordax*, of the Atlantic

coast from Virginia northward, anadromous to some extent, and otherwise very similar to the sparring. There are several true smelts of the Pacific coast of North America, as *O. thaleichthys*, the Californian smelt, and *O. dentata*, the Alaska smelt. Hence—(b) Any other species of the family *Argentinidae* related to the smelt, such as the *Hypomesus pretiosus* or *obidus*, also called *soft-smelt*, which is distinguished from the true smelts by having the dorsal fin mostly advanced beyond the ventrals and by the much smaller mouth and weak teeth. It inhabits the Pacific coast of the United States from California northward, reaches a length of about 12 inches, and is highly esteemed as a food fish. (c) In California, any species of the family *Atherinidae*, resembling the true smelt in general appearance, but provided with an anterior spinous and a posterior branched dorsal fin, and having the ventrals not far behind the pectorals. The common Californian smelt, *Atherinopsis californiensis*, reaches a length of about 18 inches, and its flesh is fine, firm, and of excellent flavor, though a little dry. It is one of the most important food-fishes of California, never absent from the markets. Other species are *Atherinopsis affinis*, the little smelt, and *Leuresthes tenuis*. (d) A fresh water cyprinoid, *Hybognathus regius*, which somewhat resembles the true smelt in form, translucency, and color, also, one of other cyprinoids, as the spawn eater and the silversides. [Eastern U. S.] (e) A gadoid fish, *Microgadus proximus*, the tom-cod of the Pacific slope. [San Francisco.] (f) The smolt, a young salmon before its visit to the sea. [Eng.] (g) The lance or lant. Smoking meat consists in exposing meat previously salted, or rubbed over with salt, to wood-smoke in an apartment so distant from the fire as not to be unduly heated by it, the smoke being admitted by flues at the bottom of the side walls. Here the meat absorbs the empyreumatic acid of the smoke, and is dried at the same time. The kind of wood used affects the quality and taste of the meat, smoke from beech and oak being preferable to that from fir and larch. Smoke from the twigs and berries of juniper, or from rosemary, peppermint, etc., imparts somewhat of the aromatic flavor of these plants. A slow smoking with a slender fire is better than a quick and hot one, as it allows the empyreumatic principles time to penetrate into the interior without over-drying the outside.

3. A fungous disease of plants, affecting especially the cereal plants, to many of which it is exceedingly destructive. It is caused by fungi of the family *Ustilaginæ*. There are in the United States two well-defined kinds of smut in cereals: (a) the *black smut*, produced by *Ustilago segetum*, in which the head is mostly changed to a black dust; (b) the *stinking smut* (called *bunt* in England), which shows only when the kernel is broken open, the usual contents being found to be replaced by a black unctuous powder. The stinking smut is caused by two species of fungus, which differ only in microscopic characters—*Tilletia tritici*, with rough spores, and *T. foetens*, with smooth spores. It is the most destructive disease of wheat known, not infrequently causing the loss of half of the crop or more. It occurs to some extent throughout all the wheat-growing regions, but is especially common in Indiana, Iowa, and adjacent States, as well as in California and Europe. The disease does not spread from plant to plant or from field to field, but the infection takes place at the time the seed sprouts. No remedy can be applied after the grain is sown, but the disease can be prevented by sowing clean seed in clean soil and covering well. Smutty seed can be purified by wetting thoroughly with a solution of blue vitriol, using one pound or more to a gallon of water. Black smut may be similarly treated. *U. Maydis* is the smut of Indian corn: *U. destruens*, of *Setaria glauca*; *U. uræolum*, of many species of *Carex*, etc. See *Ustilago*, *Tilletia*, *maize smut*, *bunt*⁴, *bunt-ear*, *burnt-ear*, *brand*, 6.

piper, = Dan. *sneppe*, snipe, = MD. *snippe*, *sneppe*, D. *snip*, *snep* = MLG. *sneppe*, *snippe* = OHG. *snephta*, *snepfo*, *snepfa*, MHG. *snepfe*, G. *schnepte* (> It. dial. *sneppe*), a snipe; prob. orig. a 'snipper' or 'snapper', from the root of *snip* or *snap*: see *snip*, *snip*.] 1. A bird of the genus *Scolopax* in a former broad sense. (a) Some or any bird belonging to the family *Scolopacidae*, having the bill straight, much longer than the head, dilated and sensitive at the end, and with a median lengthwise groove on the upper mandible near the end, the toes cleft to the base, the primaries not emarginate, and the tail-feathers barred; especially, a member of the genus *Gallinago* (*Scolopax* being restricted to certain woodcock). In Great Britain three species of *Gallinago* are called *snipe*. (1) The common snipe, or whole snipe, is *Gallinago celestis* or *G. media*, formerly *Scolopax gallinago*. (2) The great, double, or solitary snipe, or woodcock-snipe, is *G. major*. (3) The small snipe, half-snipe, or jack-snipe is *G. gallinula*. They differ little except in size. In the United States the common snipe, also called *jack-snipe* and *Wilson's snipe*, is *G. wilsoni* or *G. delicata*, about as large as *G. media*, which it very closely resembles, so that it is sometimes known as the "English" snipe, to distinguish it from various snipe-like birds peculiar to America, and also *bog-snipe*, *gutter-snipe*, *meadow-snipe*, *alewife-bird*, *shad-bird*, and *shad-spirit*. It is from 10½ to 11½ inches long and from 17½ to 19½ in extent of wings; the bill is about 2½ inches long. The upper parts are blackish, varied with bay and tawny; the scapulars are edged with tawny or pale buff, forming a pair of firm stripes along the sides of the back when the wings are closed; the lining of the wings and axillary feathers is barred regularly with black and white; the tail-feathers, normally sixteen in number, are barred with black, white, and chestnut; the fore neck and breast are light-brown speckled with dark-brown; and the belly is white. (See cut under *Gallinago*.) Snipes like these, and of the same genus, are found in most countries, and are called by the same name, with or without a qualifying term. (b) Some other scolopacine or snipe-like bird. There are very many such birds, chiefly distinguished from sandpipers (see *sandpiper*) by the length, from tattlers or gambets by the sensitiveness, and from curlews, godwits, etc., by the straightness of the bill. (1) In the United States the gray-backed or red-breasted snipe are birds of the genus *Macrorhamphus*, of which there are 2 species or varieties, the lesser and greater longbeak, *M. griseus* and *M. scolopaceus*. See *dowitcher*. (2) The grass-snipe is the pectoral sandpiper, *Actodromas maculata*. See cut under *sandpiper*. Also called *jack-snipe*. (3) The robin-snipe is the knot, *Tringa canutus*, also a sandpiper. (4) The stone-snipe is *Totanus melanoleucus*, a tattler. See cut under *yellowlegs*. (5) In Great Britain the sea-snipe is the dunlin, *Tringa or Pelidna alpina*, a sandpiper. (6) In Great Britain the summer snipe is the common sandpiper, *Actitis hypoleucos*. (7) Painted snipe are the curious birds of the genus *Rhyncchæa* or *Rostratula*. See these words. (c) A common misnomer, in various localities, of the American woodcock, *Philohela minor*: also called *common snipe*, *big snipe*, *mud-snipe*, *red-breasted snipe*, *big-headed snipe*, *blind snipe*, *whistling snipe*, *wood-snipe*. See *woodcock*. (d) A misnomer of the long-billed curlew, *R. Ridgway*. [Salt Lake valley.] (e) *pl. The Scolopacidae*; the snipe family. [The plural means either two or more birds of one kind, or two or more kinds of these birds: in the former sense, the plural is generally *snipes*; in the latter, *snipes*.]

snow above which a mountain is

covered with snow. The snow-line is

The snow-line depends not only upon
altitude, but upon the prevalent winds, the
amount of precipitation, the humidity of the
atmosphere, and the latitude. Its position
is subject to great oscillations from year to year in the same
locality. Long secular oscillations in the height of the
snow-line are evidence of corresponding oscillations of
climate. In the Alps the snow-line is at an altitude of
8,000 to 9,000 feet; in the Andes, at the equator, it is
nearly 16,000 feet.

Between the glacier below the ice-fall and the plateau
above it there must exist a line where the quantity of snow
which falls is exactly equal to the quantity annually melted.
This is the snow-line.

snow-plow (snō'plou), *n.* An implement for
clearing away snow from roads, railways, etc.
There are two kinds: one to be hauled by horses, oxen,
etc., as on a common highway, and the other to be placed
in front of a locomotive to clear the rails. A modification
of the latter is adapted to street-railroads. The snow-plow
for ordinary country roads usually consists of a frame of
boards braced together so as to form an acute angle in

front, and spread out behind to any required distance.
The machine being drawn by horses harnessed to the
center framework, the angular point enters the snow,

which is thrown off by the side-boards, and thus a free
passage is opened for pedestrians, etc. For railway pur-
poses, snow-plows are of various forms, adapted to the

character of the country, the amount of snowfall, the
tendency to drift, etc. Such plows vary in size from the
simple plows carried on the front of an engine, resem-
bling a cowcatcher with smooth iron sides, to heavy struc-
tures mounted on freight-car trucks, and pushed before
one locomotive or more, or as sometimes made, self-
propelling. In recent forms the principle of centrifugal force
has been utilized for removal of the snow. Snow-plows
are often of great size, sometimes weighing fifty tons,
and can be forced through very deep drifts.

snow-shoe (snō'shō), *n.* A contrivance attached
to the foot to enable the wearer to walk on
deep snow without sinking to the extent of
being disabled. There are two principal kinds
—the web or Canadian, and the long or Norwegian.

The Canadian is a contracted
oval in front and pointed
behind, and is from 3 to 5
feet long and from 1 to 2
feet wide, the foot being
fastened on the widest
part of the shoe by means
of thongs and so as to leave
the heel free. It has a light
rim of tough wood, on which
is woven from side to side
a web of rawhide. The Nor-
wegian is merely a thin
board, about 8 feet long
and 3 inches wide, slightly
curved upward in front;
it is especially adapted to
mountains, in descending
which by its use great speed
is attained. See *skoe*.

American Indians, a slender shaft from 5 to 9
feet long, with a head curving up at one end
and a notch at the other and smaller end; also,
the game played with this shaft.

The game is simply one of dexterity and strength. The
forefinger is placed in the basal notch, the thumb and re-
maining fingers reaching along the shaft, and the snow-
snake is thrown forward on the ice or hard snow. . . .

When the slender shaft is thrown, it glides rapidly over
the surface, with upraised head and a quivering motion,
that gives it a strange resemblance to a living creature. . . .

The game is to see which person or side can throw it
farthest, and sometimes the distance of a quarter of a
mile is reached under favorable circumstances, but I think
this rare.

It is made by grinding, in mortars or mills, the chopped leaves and stalks of tobacco in which fermentation has been induced by moisture and warmth. The tobacco is well dried previous to grinding, and this is carried sometimes so far as to give the peculiar flavor of the high-dried snuffs, such as the Irish, Welsh, and Scotch. Some varieties, as the rappes, are moist. The admixture of different flavoring agents and delicate scents has given rise to fanciful names for snuffs, which, the flavor excepted, are identical. Dry snuffs are often adulterated with quicklime, and the moist kinds with ammonia, hellebore, pearl-ash, etc.

A chemical compound in common domestic use for washing and cleansing, made by the union of certain fatty acids with a salifiable base. Fats and fixed oils consist of fatty acids combined with glycerin. On treating them with a strong base, like potash or soda, glycerin is set free, and the fatty acid combines with the strong base and forms a soap. Soap is of two kinds—*soluble* soap, in which the base is potash, soda, or ammonia, and *insoluble* soap, whose base is an earth or a metallic oxide. Only the soluble soaps dissolve readily in water and have detergent qualities. Insoluble soaps are used only in pharmacy for liniments or plasters. Of the fats, stearates make the hardest, oleates the softest soaps; and of the bases, soda makes the hardest and least soluble, and potash the softest and most soluble. Perfumes are occasionally added, or various coloring matters are stirred in while the soap is semi-fluid. White soaps are generally made of olive-oil and soda. Common household soaps are made chiefly of soda and tallow. Yellow soap is composed of tallow, rosin, and soda, to which some palm-oil is occasionally added. (See *rosin-soap*.) Mottled soap is made by simply adding mineral and other colors during the manufacture of ordinary hard soap. Marine soap, known as *salt-water soap*, which has the property of dissolving as well in salt water as in fresh, is made of palm- or cocoanut-oil and soda. Soft soaps are made with potash, instead of soda, and whale, seal-, or olive-oil, or the oils of linseed, hemp-seed, rape-seed, etc., with the addition of a little tallow. Excellent soaps are made from palm-oil and soda. A solution of soap in alcohol, with camphor and a little essential oil added to scent it, forms a soft ointment called *opodeldoc*, now superseded by soap-liniment, a similar preparation, which is liquid. Medicinal soap, when pure, is prepared from caustic soda and either olive- or almond-oil. It is chiefly employed to form pills of a gently aperient antacid action.

ning wild from gardens in
America. Its leaves and

they produce a froth when
rubbed in water, and are

is said, in some fluid
processes of washing silk
and wool imparting a pecu-
liar gloss without injur-

color. (Also called *houn-*

soar¹ (*sōr*), *v. i.* [*Early mod. E. also sore*; < ME.
soren, *sorenen*, < OF. *essorer*, *essorer*, F. *essorer*,
lay out, mount, or soar, dial. *essorer*, air clothes,
= Pr. *essorar*, *essorar* = It. *sorari*, soar, < LL. **exaurare*, expose to the air, formed < L.
ex, out, + *aura*, a breeze, the air: see *aural*.]
1. To mount on wings, or as on wings, through
the air; fly aloft, as a bird or other winged
creature; specifically, to rise and remain on the
wing without visible movements of the pinions.
The specific mode of flight is specially distinguished from
any one in which the wings are flapped to beat the air;
but the term *soaring* is also loosely applied to any light,
easy flight to a great height with little advance in any
other direction, whatever be the action of the wings, as
of a skylark rising nearly vertically from the ground. In
the case of heavy-bodied, short-winged birds which fly up
thus, the action is often specified as *rocking* or *towering*
(see these verbs). A kind of swift wayward soaring, as of

the swallow, is often called *skimming*. Soaring specifi-
cally so called, or sailing on the air, is best shown in the
flight of long-winged birds, whether their wings be either
narrow and sharp, or ample and blunt, as the albatross,
frigate, and some other sea-birds, storks, cranes, and some
other large waders, turkey-buzzards and other vultures,
eagles, kites, and some other large birds of prey. It is
capable of being indefinitely protracted, either on a hori-
zontal plane, or at a considerable inclination upward, at
least in some cases; but most birds which soar to a higher
level without beating the wings take a spiral course,
mounting as much as they can on that part of each lap
which is against the wind, and this action is usually spec-
ified as *spiriting* or *circling*.

So have I seen a lark rising from his bed of grass, and
soaring upwards, singing as he rises, and hopes to get to
heaven, and climb above the clouds.

Jer. Taylor, *Sermon*, *The Return of Prayers*, II.

2. To mount or rise aloft; rise, or seem to rise,
lightly in the air.

Phoebus rise and sink by fits: at last they *soar*
In one bright blaze, and then descend no more.

the slender *soaring* grace of Giotto's campanile, and the
quaint octagon of San Giovanni in front of them.

3. To float, as at the surface of a liquid. [*Rare.*]

cause the Chubs to sink down to the bottom with fear;

shadow affrights them again.

was of the meanest kind: the only freehold
tenure in England after the abolition of mili-

into *free* and *villain*—*free socage*, or common or simple *so-
cage*, where the service was not only certain but honorable,
as by fealty and the payment of a small sum, as of a few
shillings, in name of annual rent, and *villain socage*, where
the service, though certain, was of a baser nature. This
last tenure was the equivalent of what is now called *copy-
hold tenure*.

In *socage land*—the land, that is, which was held by
free tenure, but without military service—the contest
between primogeniture and gavel-kind was still undecided
in the thirteenth century. F. Pollock, Land Laws, p. 57.

For the present its members content themselves with the promotion of measures for the amelioration of the condition of the working classes, such as shortening the hours of labor, forbidding the employment of children in factories, and higher education for all. Social Democrats are now found in many of the countries of Europe, as well as in the United States. Since the fusion of the Lassalle and Marx groups of socialists in 1875, the social-democratic party in Germany has had remarkable development. *Social* dynamics, that branch of sociology which treats of the forces of the progress of society from one epoch to another. It concerns itself more especially with questions relating to public health, education, labor, punishment of crime, reformation of criminals, pauperism, and the like. It thus deals with the

effect of existing social forces and their result on the general well-being of the community, without directly discussing or expounding the theories or examining the problems of sociology, of which it may be considered as a branch.—*Social* statics, that branch of sociology which treats of the conditions of the stability or equilibrium of the different parts of society or the theory of the mutual action and reaction of contemporaneous social phenomena on each other, giving rise to what is called *social order*.—*Social* war, in *Rom. hist.*, the war (90–88 B.C.) in which the Italian tribes specially termed the allies (*socii*) of the Roman state fought for admission into Roman citizenship. socialism (sō'shāl-izm), *n.* [= *F. socialisme* = *Sp. Pg. socialismo* = *G. socialismus*; as *social* + *-ism*.] Any theory or system of social organization which would abolish, entirely or in great part, the individual effort and competition on which modern society rests, and substitute for it cooperative action, would introduce a more perfect and equal distribution of the products of labor, and would make land and capital, as the instruments and means of production, the joint possession of the members of the community. The name is used to include a great variety of social theories and reforms which have more or less of this character.

What is characteristic of *socialism* is the joint ownership by all the members of the community of the instruments and means of production; which carries with it the consequence that the division of the produce among the body of owners must be a public act performed according to rules laid down by the community. *Socialism* by no means excludes private ownership of articles of consumption. *J. S. Mill*, *Socialism*.

Socialism, . . . while it may admit the state's right of property over against another state, does away with all ownership, on the part of members of the state, of things that do not perish in the using, or of their own labor in creating material products. *Woolsey*, *Communism and Socialism*, p. 7.

Christian socialism, a doctrine of somewhat socialistic tendency which sprang up in England about 1850, and flourished under the leadership of Charles Kingsley, Frederick D. Maurice, Thomas Hughes, and others. The main contentions of its advocates were (1) that Christianity should be directly applied to the ordinary business of life, and that in view of this the present system of competition should give place to cooperative associations both productive and distributive, where all might work together as brothers; (2) that any other change of the laborer's life, as aimed at in most socialistic schemes, would not suffice to settle the labor question, but that there must be an inner change brought about by education and elevation of character, especially through Christianity; and (3) that the aid of the state should not be invoked further than to remove all hostile legislation. A similar scheme appeared somewhat earlier in France. The doctrines of Christian socialism, or similar doctrines under the same name, have been frequently advocated in the United States. — *Professional socialism*. Same as *socialism of the chair*. — *Socialism of the chair*, a name first used in ridicule in 1872 by Oppenheim, one of the leaders of the National Liberals for the doctrines of a school of political economy in Germany which repudiated the principle of laissez-faire, adopted in the study of political economy the historical method (which see, under *historical*), and strove to secure the aid of the state in bringing about a better distribution of the products of labor and capital, especially to bring to the laborer a larger share of this product, and to elevate his condition by means of factory acts, savings-banks, sanitary measures, shortening of the hours of labor, etc.

The term is in theological usage a general one, and includes a considerable variety of opinion. The Socinians believe that Christ was a man, miraculously conceived and divinely endowed, and thus entitled to honor and reverence, but not to divine worship; that the object of his death was to perfect and complete his example and to prepare the way for his resurrection, the necessary historical basis of Christianity; that baptism is a declarative rite merely, and the Lord's Supper merely commemorative; that divine grace is general and exerted through the means of grace, not special and personally efficacious; that the Holy Spirit is not a distinct person, but the divine energy; that the authority of Scripture is subordinate to that of the reason; that the soul is pure by nature, though contaminated by evil example and teaching from a very early age; and that salvation consists in accepting Christ's teaching and following his example. The Socinians thus occupy theologically a midway position between the Arians, who maintain the divinity of Jesus Christ, but deny that he is equal with the Father, and the Humanitarians, who deny his supernatural character altogether.

It was first isolated by Davy, in 1807, by electrolysis, and is at present obtained on a large scale by igniting sodium carbonate with charcoal. Sodium is a silver-white metal with a high luster, but it oxidizes rapidly on exposure to moist air. Heated in the air, it burns rapidly with a bright-yellow flame, very characteristic of the metal; thrown into cold water, it oxidizes, but does not become hot enough to set the evolved hydrogen on fire, as potassium does; with hot water, ignition of the hydrogen takes place. Its specific gravity at 56° is 0.9735; at the ordinary temperature it has the consistency of wax; at 204° it melts, and forms a liquid resembling mercury in appearance. Next to silver, copper, and gold, it is, of the metals, the best conductor of heat and electricity; next to cesium, rubidium, and potassium, it is the most electropositive of the metals. It is extensively used in the laboratory as a powerful reducing agent; it is closely analogous to potassium in its chemical relations. Two of its compounds are very widely diffused in nature, and of the highest importance from various points of view: these are common salt and sodium carbonate, or soda.—**Sodium bicarbonate**, a compound having the formula NaHCO_3 . It is a white crystalline powder, with a weaker alkaline taste than the other carbonate described below, and less soluble in water. Also called *soda saleratus*.—**Sodium borate**. See *borax*.—**Sodium carbonate**, a compound having the formula Na_2CO_3 , either anhydrous or containing water of crystallization. (The method of manufacture is described under *soda*.) Anhydrous sodium carbonate, or chemically pure soda, is a white powder having an alkaline taste and reaction, readily soluble in water with evolution of heat. It fuses at a dull-red heat to a clear liquid. It is used in enormous quantities in the arts for a great variety of purposes. When crystallized from aqueous solution it forms transparent crystals, called *washing-crystals*, which contain ten equivalents of water. These effloresce on exposure to air.—**Sodium chlorid**, common salt, NaCl .

See *salts*, 1.—**Sodium line**, the bright-yellow line (strictly a double line) which incandescent sodium vapor gives when viewed by the spectroscope: it corresponds to the dark absorption-line D (D_1 and D_2) of the solar spectrum.—**Sodium nitrate**. See *nitrate of soda*, under *nitrate*.

3. A mixture of fine earthy material with more or less organic matter resulting from the growth and decomposition of vegetation on the surface of the ground, or from the decay of animal matter (manure) artificially supplied. The existence of soil over any area implies a previous decomposition of the rocks, and climatic and other physical conditions favorable to the growth of vegetation. As these conditions vary, so varies the thickness of the soil. That which lies next beneath the soil and partakes of its qualities, but in a less degree, is called the *subsoil*.

Solanaceæ (*sol-ā-nā'sē-ē*), *n. pl.* [NL. (Bartling, 1830), < *Solanum* + *-aceæ*.] An order of gamopetalous plants, of the series *Bicarpellatæ* and cohort *Polemonioides*, characterized by regular flowers commonly with a plicate border, carpels with many ovules, and a straight, spiral, or coiled embryo in fleshy albumen. The sepals, petals, and stamens are each usually five, the ovary usually entire and two-celled, with an undivided style. In its plicate corolla the order resembles the *Convulsiaceæ*, which are, however, unlike it in their few-seeded carpels and usually twining habit. Its other nearest ally is the *Scrophulariæ*, to which the tribe *Solanoideæ*, by its didymous stamens and somewhat irregular flowers, forms a direct transition. The order includes about 1,750 species, perhaps to be reduced to 1,500, classed in 72 genera of 5 tribes, for the types of which see *Solanum*, *Atropa*, *Hyoscyamus*, *Cestrum*, and *Schlotheimia*. They are erect or climbing herbs or shrubs, or sometimes trees, and either smooth or downy, but rarely with bristles. They bear alternate and entire toothed or dissected leaves, often in scattered unequal pairs, but never truly opposite. The typical inflorescence is a bractless cyme, either terminal, opposite the leaves, or lateral, but not truly axillary, and sometimes converted into umbels or sessile clusters or reduced to a single flower. They are usually rank-scented and possess strongly narcotic properties, either throughout or in special organs, in *Mandragora* in the root, in most others strongly developed in the leaves, as in belladonna, tobacco, henbane, stramonium, and nightshade. In some, as the henbane, this principle is actively developed for a limited time only; in others, parts from which it is absent furnish a valued food, as the potato, tomato, and egg-plant, or a condiment, as Cayenne pepper. The order furnishes also several tonics and numerous diuretic remedies, as species of *Physalis*, *Nicandra*, *Cestrum*, and *Solanum*. Plants of this order are widely dispersed through warm climates of both hemispheres, extending beyond the tropics in North and South America, especially in the west, but less frequent in Europe and Asia. They are absent in alpine and arctic regions and in Australia. About 17 genera and 55 species are natives of the United States, chiefly in the southwest, and largely of the genera *Lucium*, *Solanum*, and *Physalis*. For other important genera, see *Lycopersicum*, *Capsicum*, *Datura*, *Nicotiana*, *Petunia*, and *Solanandra*.

solander² (*sō-lān'dēr*), *n.* [*< Solander* (see quot. and *Solandra*).] A form of box designed to contain prints or drawings. See the quotation.

A *Solander* case is the invention of Dr. Solander, of memory dear to readers of "Cook's Voyages," who used one to contain and preserve specimens for natural history, drawings, and matters of the kind. It is really a box, generally shaped like a book, one side of which, turning on hinges, serves for a lid, while the front, or fore edge of the case, is furnished with hinges to be let down, so that the fronts as well as the tops of the contents can be got at.

Solandra (*sō-lān'drā*), *n.* [NL. (Swartz, 1787), named after Daniel *Solander* (born 1736, died about 1781), a Swedish botanist and traveler.] A genus of solanaceous plants, of the tribe *Atropææ*. It is characterized by solitary flowers with a long calyx-tube, an obliquely funnel-shaped corolla with broad imbricated lobes and induplicate sinuses, five stamens, and a two-celled ovary imperfectly four-celled by false partitions, forming in fruit a pulpy berry half-protruded from the torn membranous calyx. The 4 species are all American and tropical. They are lofty climbing coarse shrubby plants, with entire smooth fleshy and coriaceous shining leaves, clustered near the ends of the branches, and very large terminal white, yellowish, or greenish flowers on fleshy pedicels. *S. grandiflora*, *S. longiflora*, and other species are sometimes cultivated from the West Indies under the name *trumpet-flower*, forming handsome greenhouse evergreens, usually grown as climbers, or, in *S. longiflora*, as small shrubs.

Solanææ (*sō-lā'nē-ē*), *n. pl.* [NL. (A. L. de Jussieu, 1789), < *Solanum* + *-ææ*.] A tribe of plants of the order *Solanaceæ*. It is distinguished by flowers with the corolla somewhat equally plicate or divided into valvate or induplicate lobes, and having perfect stamens and a two-celled ovary which becomes an indehiscent berry in fruit, containing compressed seeds with a curved embryo and slender seed-leaves not broader than the radicle. It includes 31 genera, very largely natives of South America. For some of the most important, see *Solanum* (the type), *Capsicum*, *Lycopersicum*, and *Physalis*.

solanaceous (*sō-lā'nē-us*), *a.* Belonging to the *Solanaceæ*, or especially to *Solanum*.

solanine (*sol'a-nin*), *n.* [NL., < *Solanum* + *-ine*².] A complex body, either itself an alkaloid or containing an alkaloid, the active principle of bittersweet, *Solanum Dulcamara*. It is a narcotic poison.

solano (*sō-lā'nō*), *n.* [*< Sp. solano*, an easterly wind (cf. *solanazo*, a hot, violent easterly wind, *solana*, a sunny place), < L. *solanus* (sc. *ventus*), the east wind (usually called *subsolanus*), < *sol*, sun: see *sol*¹, *solar*¹.] The Spanish name of an easterly wind.

solanoid (*sol'a-noid*), *a.* [*< NL. Solanum* + Gr. *είδος*, form.] Resembling a potato in texture: said of cancers.

Solanum (*sō-lā'num*), *n.* [NL. (Tournefort, 1700), < LL. *solanum*, the nightshade.] A genus of gamopetalous plants, type of the order *Solanaceæ*, the nightshade family, and tribe *Solanææ*. It is characterized by flowers usually with a deeply five- or ten-lobed spreading calyx, an angled or five-lobed wheel-shaped corolla, very short filaments with long anthers which form a cone or cylinder, open by a vertical pore or a larger chink, and are almost destitute of any connective, and a generally two-celled ovary with its conspicuous placenta projecting from the partition. It is one of the largest genera of plants (compare *Senecio*), and includes over 950 published species, of which perhaps 750 are distinct. Their distribution is similar to that of the order, and they constitute half or two thirds of its species. They are herbs, shrubs, or small trees, sometimes climbers, of polymorphous habit, either smooth, downy, or woolly, or even viscous. They bear alternate entire or divided leaves, sometimes in pairs, but never truly opposite. Their flowers are yellow, white, violet, or purplish, grouped in panicles or umbels cymes which are usually scorpioid, sometimes apparently racemose, rarely reduced to a single flower. The species form two groups, the subgenera *Fastigiatum* and *Leptostemonum* (Dunal, 1813). The first unarmed and with broad anthers, the other with long anthers opening by minute pores, and commonly armed with straight spines on the branchlets, leaves, and calyx. South America is the central home of the genus, and of its most useful member, the potato, *S. tuberosum*, which occurs in numerous wild varieties, with or without small tubers on the rootstocks, from Lima to latitude 45° S. in Patagonia, and northward to New Mexico. (See *potato*, *potato-rot*, and cut under *rotate* and *tuber*.) There are 15 native species in the United States, chiefly in the southwest, besides numerous prominent varieties and 5 introduced species. The seeds of many species are remarkably tenacious of life, and are therefore soon naturalized, especially the cosmopolitan weed *S. nigrum*, the common or black nightshade, the original type of the genus (for which see *nightshade*, and figure of leaf under *repand*; and compare ointment of *poplar-buds*, under *ointment*): from this the name *nightshade*

A fusible alloy used for joining or binding together metal surfaces or joints, as the edges of tin cans, jewelry, and kitchen utensils. Being melted on each surface, the solder, partly by chemical attraction and partly by cohesive force, binds them together. After cleaning the edges to be joined, the workman applies a solution of zinc in hydrochloric acid and also powdered rosin to the cleaned surfaces; then he touches the heated soldering-iron to the rosin, and holding the solder-bar and iron over the parts to be joined melts off little drops of solder at intervals along the margins, and runs all together with the hot iron. There are many of these alloys, as soft solder used for tinware, hard solder for brass and iron, gold solder, silver solder, spelter solder, plumbers' solder, etc. Every kind is used at its own melting-point, which must always be lower than that of the metals to be united, soft solders being the most fusible.

The ends of the wire are brought to the middle point, and when a current is passed through the circuit the solenoid behaves, as far as external action is concerned, like a long and thin bar magnet. For this reason, such a magnet is called a *solenoidal magnet*; and Ampère's theory of magnetism is based on the assumption that magnets and solenoidal systems of currents are fundamentally identical.

A magnetic *solenoid* is an infinitely thin bar of any form longitudinally magnetized with an intensity varying inversely as the area of the normal section [that is, the cross-section perpendicular to the length] in different parts.

=Syn. 1. Dense. 8. Stable, weighty, important.

II. *n.* 1. A body which throughout its mass (and not merely at its surface) resists for an indefinite time a sufficiently small force that tends to alter its equilibrium figure, always springing back into shape after the force is removed; a body possessing elasticity of figure. Every such body has limits of elasticity, and, if subjected to a strain exceeding these limits, it takes a set and does not return to its original shape on being let go. This property is called *plasticity*. The minimum energy required to give a set to a body of definite form and size measures its resilience. When the resilience of a body is small and masks its springiness, the body is called *soft*. Even fluids transmit shearing forces if time be allowed, and many substances will yield indefinitely to very small (but not indefinitely small) forces applied for great lengths of time. So solids that have received a small set will sometimes partially recover their figures after a long time. This property in fluids is called *viscosity*, in solids *after-effect* (German *nachwirkung*). The phenomenon is connected with a regrouping of the molecules, and indicates the essential difference between a solid and a liquid. In fluids diffusion is continually active, and in gases it produces phenomena of viscosity. In liquids it is not rapid enough to give rise to sensible viscosity, but the free motion of the molecules makes the body fluid, while the tendency of sets of molecules to continue for a while associated makes the fluidity imperfect. In solids, on the other hand (at least when not under strain), there is no diffusion, and the molecules are consequently in stationary motion or describing quasi-orbits. They thus become grouped in the mode in which they have least positional energy consistent with their kinetic energy. When this grouping is slightly disturbed, it tends to restore itself; but when the disturbance is greater, some of the molecules will tend to return to their old places and others to move on to new situations, and this may give rise to a new permanent grouping, and exhibit the phenomenon of plasticity. But if not quite sufficient for this, disturbances of the molecular motions somewhat similar to the secular perturbations of the planets will result, from which there will be no restoration for a very long time. Solid bodies are very strongly cohesive, showing that the molecules attract one another on the whole; and they are generally capable of crystallization, showing that the attractions of the molecules are different in different directions.

2. In *geom.*, a body or magnitude which has three dimensions—length, breadth, and thickness—being thus distinguished from a *surface*, which has but two dimensions, and from a *line*, which has but one. The boundaries of solids are surfaces. Besides the three round bodies (the sphere, cone, and cylinder), together with the conoids, and the pyramids, prisms, and prismatoids, the most important geometrical solids are the five Platonic and the Kepler-Poinsot regular polyhedra, the two semi-regular solids, and the thirteen Archimedean solids. The faces, edges, or summits of one solid are said to correspond with the faces, edges, or summits of another when the radii from the center of the for-

(12 to 24 are the Archimedean solids.)

mer to the mid-faces, mid-edges, or summits can be simultaneously brought into coincidence with the radii from the center to the mid-faces, mid-edges, or summits of the latter. If two solids correspond faces to summits, summits to faces, and edges to edges, they are said to be *reciprocal*. If to the edges of one solid correspond the faces or summits of another, while to the faces and summits together of the former correspond the summits or faces of another, the latter is said to be the *summital* or *facial holohedron* of the former. The regular tetrahedron is the reciprocal of itself, and its reciprocal holohedra are the cube and octahedron. The reciprocal holohedra of these, again, are the semi-regular dodecahedron and the cuboctahedron. The facial holohedron of these, again, is the small rhombicuboctahedron. The faces of the truncated cube and truncated octahedron correspond to those of the cuboctahedron. The snub-cube has faces corresponding to the cuboctahedron, and twenty-four faces which in two sets of twelve correspond to the summits of two other cuboctahedra. The faces of the great rhombicuboctahedron correspond to those of the small rhombicuboctahedron. Just as the cube and octahedron are reciprocal, so likewise are the Platonic dodecahedron and icosahedron, though they are related to no hemihedral body like the tetrahedron. Their reciprocal holohedra are the semi-regular triacontahedron and the icosidodecahedron, and the facial holohedron of these, again, is the small rhombicosidodecahedron. The faces of the truncated dodecahedron and truncated icosahedron correspond to those of the icosidodecahedron. The snub-dodecahedron has faces corresponding to those of the icosidodecahedron, and two sets of others corresponding to the summits of two other icosidodecahedra. The faces of the great rhombicosidodecahedron correspond to those of the small rhombicosidodecahedron. The faces, summits, and edges of the great icosahedron and great stellated dodecahedron correspond respectively to the faces, summits, and edges of the Platonic dodecahedron and icosahedron. The great dodecahedron and small stellated dodecahedron are self-reciprocal, both faces and summits corresponding to the faces of the Platonic dodecahedron or summits of the icosahedron. The faces of the truncated tetrahedron correspond to the faces of the octahedron or summits of the cube.

3. *pl.* In *anat.*, all parts of the body which are not fluid; as, the *solids* and fluids of the body.

—4. *pl.* In *printing*, the parts of an engraving which show black or solid in print. —Archimedean, rectangular, right solid. See the adjectives.

—Cissoidal solid, a solid generated by the rotation of the cissoid about its axis. —Kepler solid, or Kepler-Poinsot solid, a regular solid which wraps its center more than once. There are four such solids—the great icosahedron, the great dodecahedron, the small stellated dodecahedron, and the great stellated dodecahedron. Three of them were mentioned by Kepler, and all were rediscovered by Poinsot. The names here used were given by Cayley.

—Logistic solid, a solid generated by the revolution of a logarithmic curve about its asymptote. —Plastic solid, a solid substance whose limit of elasticity is far below its point of rupture, so that it can be shaped: thus, putty and wrought-iron are *plastic solids*. —Platonic solid, one of the old regular solids which wrap the center only once. They are five—the tetrahedron, the cube, the octahedron, the twenty-vertexed dodecahedron, and the icosahedron.

—Regular solid, a polyhedron whose faces are regular polygons, all alike. —Semi-regular solid, a body whose edges are all of equal length, whose faces are all alike and equally incline to one another at the edges, but whose faces are not regular polygons. Two such solids are known—the rhombic dodecahedron and triacontahedron. —Solid of least resistance. See *resistance*. —Solid of revolution. See *revolution*.

Solidago (sol-i-dā'gō), *n.* [NL. (Vaillant, 1720), < ML. *solidago*, goldenrod (*Solidago Virgaurea*), so called from its reputed vulnerary qualities, < L. *solidus*, solid; see *solid*.] 1. A genus of composite plants, the goldenrods, of the tribe *Asteroidae* and subtribe *Homochromae*, sometimes made the type of a further subdivision, *Solidagineae* (De Candolle, 1836). It is characterized by several-flowered small and radiate yellow heads, with a small flat usually alveolate receptacle, and an oblong involucre of erect rigid bracts which are closely imbricated in several rows and are without herbaceous tips. The oblong or obovoid five- to twelve-ribbed achenes bear a copious whitish pappus of long and nearly equal slender bristles. From *Aster*, which it closely resembles in technical characters, it is distinguished by its taller wand-like habit, yellow rays, smaller heads, and the absence of cordate leaves; from *Chrysopsis* and *Haplopappus* by its narrow few-flowered heads; and from *Bigelovia*, its other most

important near relative, by the presence of rays. The species have in general a very characteristic habit, being perennial herbs, usually with strictly erect unbranched stems, which bear numerous entire or serrate alternate sessile narrow stem-leaves and broader root-leaves, which taper into margined petioles. Numerous intermediate forms render many species difficult to distinguish. In the original species, *S. Virgaurea*, the golden yellow flowers are massed in small clusters which form an elongated or interrupted spike, whence the popular name *goldenrod*. The typical inflorescence, however, is a terminal pyramidal panicle of determinate development, composed of numerous recurring and scorpioid one-sided racemes, best seen in *S. Canadensis* and *S. rugosa*. In other species the flowers form a dense thyrsus of straight and terete crowded racemes, as *S. speciosa*, of the Atlantic and interior United States. A few others from the Ohio and Mississippi valleys, as *S. rigida*, produce nearly level-topped cymes. Four other cymose species were formerly separated as a genus, *Euthamia* (Nuttall, 1818), distinguished by lack of scorpioid branchlets and by their linear entire one- to five-nerved leaves, including the widely distributed species *S. lanceolata* and *S. Caroliniana* (*S. tenuifolia*), and connecting with *S. paucifloruscula*, of the Southern States and the Bahamas, formerly separated as a genus, *Chrysoma* (Nuttall, 1840), because of its shrubby stem and few-flowered heads with one to three rays. Several other species are slightly aberrant: *S. multiradiata*, of the Rocky Mountains, sometimes has twelve rays, others usually five; *S. discoida*, a racemose Gulf species, is wholly without rays and has a purplish pappus; this, with *S. squarrosa* of northern rocks and *S. petiolaris* of southern pine-barrens, varies also in the spreading tips of the involucre bracts. *S. bicolor* is remarkable for its cream-colored flowers. *S. verna*, of pine-woods near Wilmington, North Carolina, blooms in May; *S. uliginosa*, of northern peat-bogs, in July; *S. juncea* and *S. elliptica* in August; and *S. rugosa*, *S. Canadensis*, and most others mainly in September; *S. nemoralis* and *S. cre-*

sia continue well into October. The genus is one of the most characteristic of the United States, numerous both in species and in individuals, and not entirely wanting in any region. In the northern and central States it gives to the landscape much of its beauty, and is an important element of the prevailing yellow of autumn. There are nearly 100 species, of which 80, besides more than 30 important varieties, are natives of the United States, and the others are nearly all American, 9 of them occurring in Mexico, 2, 3, or 5 in South America (3 in southern Brazil, 2 in Uruguay, and 1 in Chili), and 1 in Hayti. Only 2 species are natives of the Old World, *S. littoralis*, limited to the Tuscan and Ligurian coast, and *S. Virgaurea*, which extends from Mount Parnassus north and west throughout Europe and into Siberia, Alaska, New York, and New England, in many widely differing varieties. Those of the United States are all, with 5 exceptions, confined to them and to British America (into which 32 extend), and are mainly natives of the Atlantic and central States. Numerous isolated species are southern; the northern are mostly of wider distribution and more abundant in individuals; 11 species are mainly confined to the high northern, 12 to the northeastern, 24 to the southern, 8 to the southwestern, 10 to the Pacific States; 6 belong to the Mississippi valley, of which *S. Missouriensis* is the only one widely distributed; 2 species, *S. odora* and *S. sempervirens*, extend throughout the Atlantic coast from Canada to Mexico, and the latter, the salt-marsh goldenrod, reappears at the Azores and at San Francisco. Forty-two species occur in the northeast quarter of the United States, 53 in the Southern States, and about 14 among the Rocky Mountains. *S. Canadensis*, the most numerous and most typical species, is also the one most widely diffused through the United States, followed next by *S. nemoralis* and *S. rugosa*. The species of this genus range from beyond 66° N. latitude to the city of Mexico, and from alpine summits to the sea-level; several are mostly confined to swamps, as *S. patula*, and a few to woodland borders, as *S. cæsia* and *S. bicolor*, but most are plants of dry open soil, especially *S. nemoralis*. In parts of the Atlantic coast the name *goldenrod* is locally confined to *S. odora*, the sweet goldenrod of authors, which contains in its dotted leaves an aromatic and stimulating volatile oil of an anisate odor and pale greenish-yellow color; it is also carminative and diaphoretic, and its infusion is used to relieve spasmodic pains and nausea; its dried flowers and leaves have been employed as a beverage, under the name of *Blue-Mountain tea*. *S. Virgaurea*, the goldenrod of Europe, contains an astringent and tonic principle, and was long in esteem for healing wounds,

tio(n)-, a loosing, dissolving, < *solvere*, pp. *solutus*, loose, resolve, dissolve: see *solve*.] 1. The act of separating the parts of any body; disruption; rupture; fracture; breach: as, a *solution* of continuity (see below).—2. The transformation of matter from a solid or gaseous state to the liquid state by means of a liquid called the *solvent* or *menstruum*; the state of being dissolved. The nature of the phenomenon depends upon whether chemical action is or is not present. Solution in the physical sense—the common and proper use of the word—is illustrated by dissolving sugar or salt in water, or silver in mercury; here, and in similar cases, when by the removal of the liquid (as by evaporation) the original solid is obtained, the process is essentially a change of molecular state, from the solid to the liquid, and hence accompanied by the absorption of heat; this is strikingly seen in freezing-mixtures. The word is not infrequently used, however, when the phenomenon is one of chemical combination only, as when silver dissolves in nitric acid, forming a new substance, silver nitrate; this, as is generally true of chemical union, is accompanied by the evolution of heat. The two phenomena, physical and chemical, may both be present in solution at the same time, and the line between them often cannot be sharply drawn; glacial acetic acid dissolves in water and at the same time combines with it, the liberation of heat of the chemical part of the process overbalancing the absorption of heat in the physical. The solution of a gas in a liquid, as of ammonia gas in water (also called *absorption*), is essentially the physical process of the change of the gas to the liquid, and hence is accompanied with the evolution of heat. The term *solution* is also sometimes applied to the absorption of gases by solids, as when palladium absorbs or dissolves hydrogen gas, forming a true alloy with it. The solubility of any solid is constant at a given temperature, and may be accurately determined by experiment. It may be increased or diminished by the presence of other substances in solution. The solubility of any gas also is constant under the same conditions. It varies with the temperature, the pressure, the nature of the liquid, and the matters in solution in it. In a mixture of gases, each is dissolved in the same quantity as if it were present alone under the same tension as in the mixture.

3. The liquid produced as a result of the process or action above described; the preparation made by dissolving a solid in a liquid: as, a *solution* of salt, soda, or alum; *solution* of iron, etc.—4. A liquid or dissolved state or condition; unsettled state; suspense.

Lowell, Among my Books, 1st ser., p. 313.

5. The act of solving, working out, explaining, clearing up, or settling, or the state of being solved, explained, cleared up, or settled; resolution; explanation: as, the *solution* of a difficult problem or of a doubt in casuistry.

It is according to nature no man to do that whereby he shulde take . . . a praye of a nother mannes ignorance. Of this matter Tulli writeth many propre examples and quicke *solutions*.

$$(c_2 - c_3) \sqrt{H - c_1 T} - (c_1 - c_3) \sqrt{H - c_2 T} - (c_1 - c_2) \sqrt{H - c_3 T} = 0.$$

A germ that is three-layered—that is, consists of an ectoderm and an endoderm, with mesoderm between them—in most animals becomes four-layered by a splitting of the mesoderm into two layers, the outer or somatopleural and the inner or splanchnopleural, separated by a space which is the body-cavity or coelom. The somatopleure thus constitutes usually the great mass of the body, or the "flesh and bones" of ordinary language, together with its vessels, nerves, and other special structures—not, however, including the cerebrospinal axis of a vertebrate, which is derived from an inversion of ectoderm—while the splanchnopleure forms a portion of the substance of the intestinal tract and its annexes. somatotropism (sō-mā-tōt'rō-pizm), *n.* [*< somatotropic + -ism.*] In *bot.*, a directive influence exerted upon growing organs by the mass of the substratum upon which they grow. This influence is not wholly due to the mere physical attraction between them, but is the result of a stimulating effect on what has been called the *nerve-motility* of the organ. Growing organs may be divided, according to their response to this influence, into two classes, the *positively somatotropic*, or those which tend to grow perpendicularly inward into the substratum, and *negatively somatotropic*, or those which tend to grow perpendicularly outward from the substratum.

3. In *logic*, at least one, perhaps all; but a few logicians sometimes employ a semidefinite *some* which implies a part, but not all. As commonly used in *logic*, a statement about *some* of a class, say that "some S is P" means that it is possible so to select an S that it shall be P; while "every S is P" means that whatever S be taken, it will be P. But when *some* and *every* occur in the same statement, it makes a difference which is chosen first. Thus, "every man knows some fact" may mean (1) that, first choosing any man, a fact may then be found which that man knows (which may be expressed by saying that every man knows some fact or other); or it may mean (2) that a fact may be first selected such that, then, taking any man, he will know that fact (which may be expressed by saying that all men know some certain fact). When several *some*s and *alls* occur in the same statement, ordinary syntax fails to express the meaning with precision, and logicians resort to a special notation.

somital (sō'mi-tāl), *a.* [*< somite + -al.*] Same as *somitic*.

somite (sō'mit), *n.* [*< Gr. σῶμα, body, + -ite².*] An actual somatome; any one morphological segment of an articulated body, such a body being viewed as composed of a longitudinal series of somites; an arthromere or metamere of an articulate invertebrate or a diarthromere of a vertebrate; such a segment considered with or without the appendages it may possess; in the latter restricted sense, a metamere minus its appendages, or a segment of the soma or trunk without the limbs it may bear. The term sometimes extends to ideal somatomes, or to the metameres of which an organism is theoretically assumed to consist; but it is especially applied to the actual segments of such invertebrates as insects, crustaceans, and worms, whose body-rings are usually evident, though some or other of them may coalesce, as into a cephalothorax, etc. In such cases the primitive or morphological somites are usually recognized and reckoned by their respective pairs of appendages. Separate somites, continued throughout the body, are evident in the rings of earthworms and other annelids. In arthropods the typical number of somites is supposed to be twenty or twenty-one, numbers often actually recognizable. In insects the head is assumed to have six or seven somites, the thorax has normally three (see *prothorax*, *mesothorax*, and *metathorax*), and the abdomen is supposed to have ten or eleven. Each of these somites is invested and indicated by a body-ring or crust of integument, primitively or typically composed of eight sclerites, which may variously coalesce with one another, or with pieces of another somite, or both. Those sclerites which ordinarily remain distinct, and thus can be identified, take special names, as *tergite*, *pleurite*, *sternite*, *sotum*, *præscutum*, etc., *epimeron*, *epipleuron*, etc. Appendages of somites are limbs in the broadest sense, under whatever modifications; and these modifications are usually greatest at the cephalic and caudal ends of the body, as into eyestalks, antennæ, palpi, mandibles, maxillæ, maxillipeds or gnathopodites, etc., of the head, and stings, claspers, or other anal armature. Intermediate somitic appendages are ordinary legs and wings, as of the thorax of insects, and the pereopods, pleopods, chelæ, rhipidura, telson, etc., of the thorax and abdomen of crustaceans. In worms such appendages chiefly occur in the form of parapodia (neuropodia and notopodia). See *sclerite*, and *cut*, under *Amphitoe*, *Apus*, *Buthus*, *Scorpionidae*, *Blattidae*, and *Cockroach*.

somitic (sō-mit'ik), *a.* [*< somite + -ic.*] Having the character of a somite; somatonic; metameric; of or pertaining to somites: as, the *somitic* divisions of the body; a *somitic* ring or joint; a *somitic* appendage.

The sleeping condition is shown by the absence of the usual reaction to sense-impressions, and usually by the failure to recall what has been done during the somnambulist period. With many recent writers, however, the word is used, quite independently of any consideration of movements which the somnambulist may or does execute, as nearly synonymous with *trance*, *mesmerization*, or *hypnotism*, and exactly so with *somnolism*. It is generally considered under the two main conditions of the idiopathic, spontaneous, or self-induced and the artificial or induced. Compare *somnolism*. Also called, rarely, *noctambulism*.

In *somnambulism*, natural or induced, there is often a great display of intellectual activity, followed by complete oblivion of all that has passed.

Somnambulism is, as a rule, a decidedly deeper state than the lighter stage of hypnotism.

Sung by flaming tongues above.

R. Robinson, Come, Thou Fount of Every Blessing.

Specifically.—2. A short poem in fixed form, limited to fourteen lines with a prescribed disposition of rhymes. The form is of Italian origin. A sonnet is generally written in decasyllabic or five-foot measure; but it may be written in octosyllabics. It consists of two divisions or groups of lines—(1) a major group of eight lines or two quatrains, and (2) a minor group of six lines or two tercets. The quatrains are arranged thus: a, b, b, a; a, b, b, a; the tercets, either c, d, c, d, c, d, or c, d, e, c, d, e. In modern French examples the order of the tercets is generally c, d, e, d, e. There are various deviations from the sonnet as thus described; but by purists the above is regarded as the orthodox form, established by long practice and prescription, all others being ranked simply as quatrains, or what Lamb called *fourteeners*. With regard to the material of the poem, it is generally considered that it should be the expression of a single thought, idea, or sentiment.

I can best allow to call those *Sonnets* which are of fourtene lynes, eury line conteyning tenne syllables.

orous mammals, the shrews. They are of terrestrial, sometimes natorial, habits, with a long and narrow skull without zygomatic arches or postorbital processes, annular tympanic bones, no symphysis pubis, the fore limbs not specially modified as in the moles, the tibia and fibula united, and the lower teeth 12 (in one genus 12

or 14). The lower incisors are long, proclivous, and usually notched; in the upper teeth the median incisors are large, and have a basal snag or cusp, appearing as if double (but see *soricident*); no canines are specialized, and the premolars are variable; the molars are large and multicuspidate. The total number of the teeth varies from twenty-six to thirty-two. The family is well marked, with little range of variation, though the species are so numerous. The shrews are all small animals, some being the smallest known mammals, and have the general appearance of mice, though with more pointed snout. The rather numerous (about 12) genera fall in two groups or subfamilies, *Soricinae* and *Crocidurinae*.

soricident (sō-ris'i-dent), *a.* [*L. sorice* (*soric-*), a shrew, + *dent* = *E. tooth*.] Having or noting a dentition like that of shrews. This dentition is unique in some respects. Soricident Teeth of Common Shrew, *Sorex araneus*, enlarged seven times. 1, large two-toothed anterior upper incisor; 2, 3, 4, 5, succeeding upper incisors; to *mpx*, line of obliterated maxillary premaxillary suture; 6, first maxillary tooth, technically a canine, unspecialized and resembling the preceding incisor; *pm1*, minute first premaxillary; *pm2*, large second premaxillary. In the lower jaw, 1, very large serrated anterior incisor; 2, 3, 4, following teeth to the one opposite *pm2*; other teeth omitted.

alone to be so named, and have occasioned great uncertainty in the dental formulae of the several genera of shrews. Determination of the position of the suture has shown, however, that several other pairs of teeth besides the specialized median upper pair are inserted in the premaxillary, and are therefore incisors; that the foremost pair of maxillary teeth (technically canines) are never specialized, and always small, and that these are followed by one or two pairs of premolars, constantly succeeded by three pairs of true molars. The constancy in number of the under teeth (twelve, with some anomalous exceptions) is also remarkable, and the total variation is only from twenty-six to thirty-two among all the genera. The eight upper incisors of several genera are a number unique among placental mammals; and the soricident dentition is, on the whole, in proportion to the size of the animals, the most formidable known among mammals, of greater relative power than that of any carnivore. See *Soricinae*.

Animals also, and even plants, have been thought to have souls. Primitive peoples identify the soul with the breath, or something contained in the blood. Separated from the body, it is supposed to have some imperfect existence, and to retain the form of the body as a ghost. The verses of Davies (see below) enumerate most of the ancient Greek opinions. The first is that of Anaximander and of Diogenes of Apollonia; the second is that of Heraclitus; the third is that of Empedocles; the fourth is that attributed to Empedocles by Aristotle; the fifth is that of Democritus and other Pythagoreans, as Simmias in the "Phædo"; the sixth is attributed wrongly to Galen; the seventh is that of Democritus and the atomists; the eighth is attributed by some authorities to the Pythagoreans; and the ninth is that of the Stoics. Aristotle makes the soul little more than a faculty or attribute of the body, and he compares it to the "axness" of an ax. The scholastics combined this idea with that of the separability and immortality of the soul, thus forming a highly metaphysical doctrine. Descartes originated distinct metaphysical dualism, which holds that spirit and matter are two radically different kinds of substance—the former characterized by consciousness, the latter by extension. Most modern philosophers hold to monism in some form, which recognizes only one kind of substance. That the soul is immortal is a very ancient and widely diffused opinion; it is also commonly believed that the soul has no parts. A soul separated from the body is commonly called a *spirit*, not a *soul*. In biblical and theological usage 'soul' (*nephesh, psyche*, also rendered 'life') is sometimes used for the non-corporeal nature of man in general, and sometimes, in distinction from *spirit*, for the lower part of this non-corporeal nature, standing in direct communication with the body, and regarded as the seat of the emotions, rarely of will or spirit. Some theologians minimize the distinction between *soul* and *spirit*, making them mere aspects or relations of the same substance, while others have made them distinct substances or distinct entities.

For soule is forme, and doth the bodie make.

All Souls' day, in the *Rom. Cath. Ch.*, the 2d of November, a day kept in commemoration of all the faithful departed, for the eternal repose of their souls, to which end the mass and offices of the day are directed. It is the day following the feast of All Saints.—**Apparitional soul**.

As long as the soul was supposed to be a material thing (which was the usual ancient opinion), it was naturally believed to have a distinct place. Later the knowledge of the functions of the nervous system, and their centralization in the brain, showed that the soul was more intimately connected with that than with other parts of the body; and it was vaguely supposed that the unity of consciousness would in some measure be explained by the hypothesis of a special seat of the soul in the brain. The commonest primitive notion was that the soul was resident in the blood or in the heart. Either the whole soul or its parts were also located in the bowels, bones, liver, gall, kidneys, and other organs. The doctrine that the soul is in the brain seems to have originated in Egypt, and found many partial adherents in antiquity, but was not generally accepted before modern times. The Neoplatonists held that the soul is wholly in the whole body and wholly in every part. Descartes placed the soul in the pineal gland, and other physiologists of the seventeenth century located it in different organs connected with the brain. Leibnitz introduced the theory that it resides at a mathematical point, which has found eminent supporters, some of whom regard this point as movable. Others hold that any conception of consciousness which forces its adherents to such a conclusion ought to be considered as reduced to an absurdity. Recent observations concerning multiple consciousness strengthen indications previously known that the unity of consciousness is somewhat illusory; and the anatomy of the brain does not support the notion of an absolute centralization of the power of forming ideas.—**Sentient soul**, the soul as affected by the senses, or as possessing sentience. = **Syn. 1 and 2. 3. To descend to the bottom; dive: said of fish and other marine animals. When a sperm-whale sounds, the fore parts are lifted a little out of water, a strong spout is given, the nose is dipped, the back and small are rounded up, the body bends on a cross-axis, the flukes are thrown up 20 or 30 feet, and the whale goes straight down head first, in less than its own length of water.

sound⁴ (sound), *n.* [= D. G. Dan. *sonde* = Sw. *sound*, *< F. soude*, a probe, a sounding-lead, = Sp. Pg. *sonda*, a sound; from the verb: see *sound*⁴, *v.*] In *surg.*, any elongated instrument, usually metallic, by which cavities of the body are sounded or explored; a probe; specifically, an instrument used for exploring or dilating the urethra, or for searching the bladder for stone.

sound⁵ (sound), *n.* [*< ME. sounde* (with excrement *sb*), *sonn, sowen, souene, son*, *< OF. sonn, son, sun, F. son* = Pr. *son*, so = Sp. *son* = Pg. *son* = It. *suono* = Icel. *sonn*, a sound, *< L. sonus*, a sound; cf. Skt. *svana*, sound, *< scan*, sound. Cf. *sound*⁵, *v.*, and see *assonant, consonant, dissonant, resonant, person, parson, resonant, sonata, sonnet, sonorous, sound, unison*, etc.] **1.** The sensation produced through the ear, or organ of hearing; in the physical sense, either the vibrations of the sounding-body itself, or those of the air or other medium, which are caused by the sounding-body, and which immediately affect the ear. A musical sound, or tone, is produced by a continued and regular series of vibrations (or, in the physical sense, may be said to be these vibrations themselves); while a noise is caused either by a single impulse, as an electrical spark, or by a series of impulses following at irregular intervals. A sounding-body is a body which is in such a state of vibration as to produce a sound (see *vibration*). Thus, a tuning-fork, a bell, or a piano-string, if struck, will, in consequence of its elasticity, continue to vibrate for some time, producing, in the proper medium, a sound; similarly, the column of air in an organ-pipe becomes a sounding-body when a current of air is continually forced through the mouthpiece past the lip; again, an inelastic body, as a card, may become a sounding-body if it receives a series of blows at regular intervals and in sufficiently rapid succession, as from the teeth of a revolving cog-wheel. The vibrations of the sounding-body are conveyed to the ear by the intervening medium, which is usually the air, but may be any other gas, a liquid (as water), or an elastic solid. The presence of such a medium is essential, for sound is not propagated in a vacuum. The vibrations of the sounding-body, as a tuning-fork, produce in the medium a series of waves (see *wave*) of condensation and rarefaction, which are propagated in all directions with a velocity depending upon the nature of the medium and its temperature—for example, the velocity of sound in air is about 1,090 feet per second at 32° F. (0° C.), and increases slightly as the temperature rises; in other gases the velocity varies inversely as the square root of the density; it is consequently nearly four times as great in hydrogen. In liquids the velocity is greater than in air—for water, somewhat more than four times as great. In solids the velocity varies very widely, being relatively small in inelastic substances like wax and lead, and very great (two to three miles per second) in wood and steel. Sound-waves may differ (1) in their wavelength—that is, in the number of vibrations per second; (2) in the amplitude of the motion of the particles forming them; and (3) in their form, as to whether they are simple, and consist of a single series of pendulum-like vibrations, or are compound, and formed of several such series superimposed upon each other. Corresponding to these differences in the sound-waves, the sounds perceived by the ear differ in three ways: (1) They differ in *pitch*. If the sound-waves are long and the number of vibrations few per second, the pitch is said to be *low* and the sound is called *grave*; as the number of vibrations increases, the pitch is said to *rise* and the sound to be *higher*; if the number of vibrations is very great and the length of the waves correspondingly small, the sound becomes shrill and piercing. It is found that the vibrations must be as numerous as 24 per second in order that the ear may be able to unite them as a continuous sound. Similarly, if the vibrations exceed 30,000 to 40,000 per second, they

cease to produce any sensation upon the ear. (2) Sounds differ in *intensity or loudness*. Primarily the intensity of the sound depends upon the amplitude of the vibrations; it diminishes with the square of the distance from the sounding-body; it also diminishes as the density of the air or other medium decreases, and is increased by the proximity of a sonorous body which can vibrate in unison with it. (3) Sounds differ in *quality or timbre*, that property by which we distinguish between the same tone as sounded upon two different musical instruments, as a piano and a violin. This difference is due to the fact that a note produced by a musical instrument is in general a compound note, consisting of the fundamental note, the pitch of which the ear perceives, and with it a number of higher notes of small intensity whose vibrations as compared with the fundamental note are usually as the numbers 2, 3, 4, 5, 6, etc. These upper notes, harmonics or over-tones (see *harmonic*), blend with the fundamental note, and upon their number and relative intensity, consequently, the resultant combined effect upon the ear, or the quality of the note, depends. Sound-waves may, like light-waves, be reflected from an opposing surface (see *reflection, echo, resonance*); they may be refracted, or suffer a change of direction, in passing from one medium to another of different density; they may suffer diffraction; and they may also suffer interference, giving rise to the pulsations of sounds called *beats*. See *beat*¹, 7.

2. A particular quality or character of tone, producing a certain effect on the hearer, or suggesting a particular cause; tone; note; as, a joyful sound; a sound of woe.

Sound is a general word, covering noise and intelligible impressions upon the auditory nerves: as, the sound of cannon, of hoofs, of a trumpet, of prayer. Tone is sound regarded as having a definite place on the musical scale, or as modified by feeling or physical affections, or as being the distinctive quality of sound possessed by a person or thing permanently or temporarily: as, his tones were those of anger; a piano of peculiarly rich tone. For technical distinctions, see *def. 1* above, noise, and tone.

'that which is drawn out,' < *√ spa*, draw out; cf. *Gr. σπᾶν*, draw, draw out, *Skt. √ sphā*, fatten. Cf. *span*¹, *spade*¹.] 1. The general receptacle of things; room, (a) as a character of the universe, (b) as a cognition or psychological phenomenon, (c) as a mathematical system. That which is real about space is that the manifoldness of the universe is subject to certain general laws or limitations. In this respect it is like any other uniformity of nature; it is peculiar only in the peculiar way in which we view it—namely, in this, that instead of thinking it, as we do other laws, as abstract and general, we seem to see it, we individualize it and its parts. This peculiarity does not, however, constitute the cognition of space as entirely *sui generis*, for there is a tendency to individualize other laws. The conception of space is formed, or at least connected with objects, by means of the so-called local signs, by which the excitation of one nerve-terminal is distinguishable from a similar excitation of another, and which are analogous to the signs by which we distinguish present experiences from memories, imaginations, and expectations. These local signs are also the origin of our idea of individuality; so that it is not strange that this mode of being becomes attributed not merely to moving objects, but to the space and time that constitute the law of motion. The celebrated doctrine of Kant was that space is a form of pure intuition—that is, an idea imported by the mind into cognition, and corresponding to nothing in the things in themselves (though he did not hold that special spatial relations were altogether illusory)—just as color is a quality of sensation which in its generality corresponds to nothing in the object, though differences of color correspond to differences in objects. That this intuition of space is individual, not general, and that no outward intuition is possible except under this form, were points also insisted upon by Kant. At present there are, broadly speaking, two views of space-perception. One is the great doctrine of Berkeley—worked out in different directions by J. S. Mill, Helmholtz, Lotze, Wundt, and others—that the idea of space is evoked under the combined influence of retinal sensations and of muscular sensations of motion, in a manner analogous to that by which the laws of dynamics have been evolved from experience. This is the theory which, under one modification or another, is held by almost all modern scientific psychologists. Some competent writers, however, oppose this, holding that "all our sensations are positively and inexplicably extensive wholes." This opinion conflicts with the usual one only in so far as it clings to the inexplicability and irrationality of space. The vulgar conception of space as a sort of thing or substance of a different category from material things, through which the latter move without sensible resistance, is acceptable to mathematicians, who find that such a construction lends itself remarkably to their diagrammatic reasoning. For the geometer, space is primarily a system of points having the following properties: (1) It is continuous. See *continuity*, 2. (2) It is unlimited, whether the part at a finite distance from a given point be limited or not. (3) It has three dimensions—that is, a set of three numbers varying continuously may be placed in continuous one-to-one correspondence with the points of space. By a continuous correspondence is meant one in which a continuous variation in one member will correspond in every case to a continuous variation in the other. (4) All the points of space have perfectly similar spatial relations. (5) It is possible for a rigid body to move in space, and such a body is fixed by the fixation of three points, but not fewer. (6) Any figure may be magnified while preserving the proportionality of all its lines. Geometers often imagine these properties to be modified. In particular, they use the hypothesis of a space of four or more dimensions. They also often suppose the principle of similar figures, or, what is the same thing, the doctrine of parallels, to be false, thus producing what is known as the *non-Euclidean geometry*. This is of various kinds.

The full extent or course over which anything is stretched or prolonged; the space or time covered or included between terminal points; entire reach from end to end or from side to side: as, the *span* of life; the *span* of a bridge. As used of physical things, *span* is understood as the actual or net space or distance between bounding lines or surfaces; hence, the *span* of an arch is the length of the opening between the inner faces of its abutments. Compare def. 2. Often used figuratively.

The brief *span* of Roman literature, strictly so called,
was suddenly closed under a variety of influences.

And larger privilege of life than man.

2. A part or division of something between terminal points: as, a bridge of ten *spans*. In this sense a span would comprise the distance from the middle line of one pier or support to that of the next, the whole number of spans including the entire length of the structure. [The decision of the case referred to in the first quotation turned upon the distinction between senses 1 and 2.]

The word *span* does not, even in architecture, always
mean a part of a structure. It is, perhaps, as often used
to denote the distance or space between two columns.
Such is the obvious import of the term as used in the act
under consideration, not merely as a part of the structure
itself, but the measure of the distance between the piers
of the bridge.

U. S. Supreme Ct., March, 1888. (Judge Lamar.)

The channel *spans* were built out from the central pier
and from the adjacent flanking *spans* without the use of

to 8.6 for numerals. *Span* increases not only with age,
but with rank in class, and it is suggested that a "stan-
dard *span*" be added to the items for anthropometric mea-
surement. *Amer. Jour. Psychol., I. 193.*

4. As a measure, originally, the extent between the tips of the thumb and little finger when stretched out: the oldest use of the word in English. The *span* belongs to the system of long measure to which the cubit and fingerbreadth belong. It has always been considered as half a cubit, and still is so in several countries of Asia. The English *span* is 9 inches. The Swedish *spann* is an entirely different kind of measure.

A dog of a domestic breed, of medium and small sizes, with a long silky and usually curly coat, long, soft, drooping ears, feathered tail and stern, of docile, timid, and affectionate disposition, much used for sporting purposes and as pets. The most usual colors are liver and white, red and white, or black and white, in broken or massed areas, sometimes deep brown or black on the face or breast, with a tan mark over the eye. Spaniels sport or are bred into many strains, and three classes of them are sometimes distinguished: *land- or field-spaniels*, including the cocker and springer; *water-spaniels*; and *toy spaniels*, as the King Charles and the Blenheim. The English spaniel is a superior and very pure breed; and, although the name *spaniel* would seem to indicate a Spanish origin, it is most probably indigenous. This dog was used in the days of falconry to start the game. The King Charles is a small black-and-tan variety of the spaniel; the Blenheim is similar, but white marked with red or yellow; both should have a rounded head with short muzzle, full eyes, and well-fringed ears

and feet. The Maltese dog and the lion dog are also small toy spaniels, used as lap-dogs. The water-spaniels, large and small, differ from the common spaniel in the roughness of their coats, and in uniting the aquatic propensities of the Newfoundland dog with the fine hunting qualities of their own race. Leading strains of the springers are the Clumber, Norfolk, and Sussex, in different colors. 2. Figuratively, a mean, cringing, fawning person; a blindly submissive follower: from the characteristics of the spaniel in relation to its master, or when in a state of fear.

He, unhappy man! whom your advancement
Hath ruin'd by being *spaniel* to your fortunes,

Electric spark, the luminous effect produced when a sudden disruptive electrical discharge takes place between two charged conductors, or between two conductors at different electric potentials. The length of the spark depends primarily upon the difference of potential of the two charged bodies; it is hence in general a conspicuous phenomenon with high-potential frictional electricity, and not with ordinary voltaic currents. See *electricity*.—*Fairy sparks*. See *fairies*.

The production of sparks is due to the formation of a small arc between the extremities of the broken conductor, and also to self-induction in the circuit. Sparking often takes place between the collecting brushes and the commutator of the dynamo. It is injurious to the machine, aside from the actual dissipation of energy which it involves. It also occurs to an injurious degree in other electrical apparatus in which currents are frequently interrupted. Various measures are resorted to for the purpose of reducing it to a minimum or avoiding it altogether. See *spark-arrester*, 3.

earn. Cf. *sparver, spavin*.] 1. The house-
sparrow, *Passer domesticus*, a fringilline bird
of Europe, which has been imported and
naturalized in America, Australia, and other
countries. It is about 6 inches long and 9½ in extent
of wings. The upper parts of the male are ashy-gray,
boldly streaked on the back with black and bay; there
is a dark-chestnut or mahogany spot on each side of
the neck; the lesser wing-coverts are chestnut; the
median are tipped with white, forming a wing-bar; the
greater coverts and inner secondaries have a black
field bordered with gray; and the lower parts are ashy
or gray, with jet-black on the throat, spreading on the
breast, and bordered on the side of the neck with white.
The female is similar, but more plainly feathered, lack-
ing the distinctive head-markings of the male. The
sparrow is a conirostral granivorous bird, whose food is
principally seeds and grain, yet it has been introduced
in many countries for the purpose of destroying noxious
insects. It is extremely hardy, pugnacious, and prolific,
rearing several large broods annually. Of all birds the
sparrow naturally attaches itself most closely to man, and
easily modifies its habits to suit artificial conditions of
environment. It is thus one of several animals, as rats,
mice, and other vermin, well fitted to survive under what-
ever conditions man may offer or enforce; hence it wins
in competition with the native birds of the foreign coun-
tries where it naturalizes, without as readily developing
counteractive agencies to check its increase. It speedily
becomes a pest wherever introduced, and seldom destroys
noxious insects to any appreciable extent. It was brought
into the United States from Germany about 1869, and is
now probably more numerous than any single native bird.
In New York city thousands of sparrows are sold and
eaten as reed-birds. See cut under *Passer* 2.

2. Some or any fringilline bird resembling the
sparrow, as *Passer montanus*, the tree-sparrow;
one of various finches and buntings, mostly of

like birds, mostly of homely streaked coloration. Chip-
ping- or field-sparrows belong to the genus *Spizella*;
crown-sparrows to *Zonotrichia*; fox-sparrows to *Passer-
ella*; grasshopper-sparrows to *Coturniculus*; the grass-
sparrow to *Pooecetes*; the lark-sparrow to *Chondestes*; sage-

parts of the country, and is known in books as the *rusty-
crowned falcon* and *prairie-hawk*. It is 10 or 11 inches
long, and from 20 to 23 in extent of wings. The adult is
ashy-blue on the crown, with a chestnut spot; on the back
cinnamon-rufous, the male having few black marks or
none, and the female numerous black bars. The wing-
coverts in the male are ashy-blue, usually spotted with
black; in the female cinnamon barred with black. The
tail is bright-chestnut, in the male with a broad subter-
minal black band, and the outer feathers mostly white
with black bars; in the female barred throughout with
black. The under parts are white, variously tinted with
buff or tawny, in the male with few black spots if any;
in the female with many dark-brown stripes. The bill is
dark horn-blue; the cere and feet are yellow or orange.
It is an elegant and spirited falcon, breeding in hollows
of trees, building no nest, but often taking possession of
a woodpecker's hole. The female lays five, six, or seven

subspheeroidal eggs, 1½ inches long by 1¼ inches broad, of a buffy or pale-yellowish ground-color, spotted and splashed all over with dark brown. Several similar sparrow-hawks inhabit America, and various other species, of both the genera named, are found in most parts of the world.

United States, one in South America beyond the tropics, and one in the islands of Trieta-da Cunha, St. Paul, and Amsterdam. They are rigid reed-like grasses rising from a tufted or creeping base, with scaly root-rhizoids, very smooth sheaths, and long convolute leaves sometimes flattened at the base. Book-names for the species are *marsh-grass, cord-grass, and salt-grass*; four of them are among the most conspicuous maritime grasses of the United States. *S. polytachya*, the largest species, is known locally on a broad stiff panicle often of fifty spikes, is known locally on the coast as *creek-thatch* and *creek-stuff*, from its growth in creeks or inlets of salt water, and from its use, when cut, as a cover for stacks of salt-hay and as bedding in stables. (See also *salt reed-grass, under reed-grass.*) *S. cynosuroides* is the cord-grass of fresh-water lakes and rivers, smaller, attaining a height of about 6 feet; it occurs from the Atlantic to the Pacific, and in great quantities along the Mississippi; a superior brown wrapping-paper has been made from it. *S. juncea*, a low turf-forming species with diminutive three- to five-ranked inflorescence, sometimes called *rush salt-grass*, covers large tracts of salt-marsh on the Atlantic coast, is recommended for binding wet sands, and yields a tough fiber from its leaves. *S. stricta*, the salt-marsh grass, with very different inflorescence, bears its numerous branches rigidly appressed into a single long and slender erect spike, or sometimes two, when it is called *twin-spike grass*. It is said to be also used as a durable thatch; it is succulent and is eagerly eaten by cattle, imparting to their milk, butter, and flesh a strong rank flavor locally known as a "thatchy" taste.

Spartium (spär'shi-um), *n.* [*< NL. (Linnæus, 1737), < L. spartum, sparton, < Gr. σπάρον, Spanish broom: see spart, esparto.*] A genus of leguminous plants, of the tribe *Genisteæ*, type of the subtribe *Spartieæ*. It is distinguished from the related genus *Genista* by a somewhat spathaceous calyx with very short teeth, by acuminate and incurved keel-petals, and by a narrower pod. The only species, *S. juncea*, is a native of the Mediterranean region and of the Canary Islands, known as *Spanish broom*, now naturalized in various parts of tropical America and long cultivated in gardens. It is a shrub with numerous long, straight, rush-like branches, which are green, polished, and round—not angular like the similar branches of the Irish broom. They are commonly without leaves; when these are present, they are composed each of a single leaflet and are without stipules. The handsome pea-like flowers form terminal racemes; they are yellow, fragrant, and highly attractive to bees, and are the source of a yellow dye. The branches are used to make baskets and fasten vines in vineyards; they yield by maceration a fiber which is made into cord and thread, and in Italy and Spain into cloth. The seeds in small doses are diuretic and tonic; in large, emetic and cathartic.

3. [cap.] The title of the presiding officer in the British House of Commons, in the House of Representatives in the Congress of the United States, in the lower houses of State legislatures in the United States, and in British colonial legislatures; also of the Lord Chancellor of Great Britain as presiding officer of the House of Lords. The Speaker of the House of Commons is elected in each Parliament from its members, with the royal concurrence, generally without regard to politics, and may preside in successive Parliaments of opposite political character. His powers (which have been much diminished in the course of time) are limited to the pres-

the regularity of the vote under the system of the speaker's vote in case of a tie. The speaker's vote is also in the case of a tie, and has, in addition to the power of appointing all members of the committee, the power of appointing all members of the committee, and of participating in all questions—rights exercised, however, in a very limited extent. He is thus in a position to exercise a very important influence, and the office is consequently regarded as of great power and influence.

I hear that about twelve of the Lords met and had chosen my Lord Manchester speaker of the House of Lords. *Papers, Diary, April 26, 1690.*

In the Lower House the Speaker of the Tudor reigns in very much the same position as the Chancellor in the Upper House. He is the manager of business on the part of the crown, and probably the nominee either of the king himself or of the chancellor.

Spears have been used as warlike weapons from the earliest times, and were the principal reliance of many ancient armies, as those of the Greeks, while in others they were used coordinately with the bow and the sword. They are represented by the bayonet in modern armies, though some use is still made of spears, of which javelins and lances are lighter, and pikes heavier, forms. Special, Especial, Particular, Peculiar, Specific.** *Special* is more common than *especial*, which has the same meaning; but *especially* is for rhetorical reasons (because it occurs most frequently at the beginning of a dependent clause, where usually an unaccented particle occurs, and where, therefore, a word with an accent on the first syllable is instinctively avoided) much more common than *speciality*. The *special* comes under the *general*, as the *particular* comes under the *special*. A *special* favor is one that is more than ordinary; a *particular* favor is still more remarkable; a *peculiar* favor comes very closely home. When we speak of any *particular* thing, we distinguish it from all others; when we speak of a *specific* fault in one's character, we name it with exactness; a *special* law is one that is made for a *particular* purpose or a *peculiar* case; a *specific* law is either one that we name exactly or one that names offenses, etc., exactly.

Cf. *specialty*, a doublet of *speciality*, as *personality*, *reality*, etc., are of *personality*, *reality*, etc.] 1. A special characteristic or attribute; a distinctive feature, property, or quality; a condition or circumstance especially distinguishing a class or an individual. [In this abstract sense *speciality* is preferable to the form *specialty*, on the analogy of *personality*, *reality*, and other words of similar tenor as related to *personality*, *reality*, etc. The distinction, so far as it exists, is accidental; the syncope form, in these pairs, is more vernacular, the full form more recent and artificial.]

Maine, Early Law and Custom, p. 18.

2. The state of being or becoming specialized; a condition of fixed or developed differentiation, as of parts, organs, or individuals, with reference to form, appearance, function, etc.

That there is (in women) . . . a mental *specialization* joined with the bodily *specialization* is undeniable; and this mental *specialization*, though primarily related to the rearing of offspring, affects in some degree the conduct at large.

H. Spencer, Study of Sociol., p. 375.

3. In *biol.*, that evolutionary process whereby parts or organs primitively indifferent or of common character become differentiated in form or function (usually in both); also, the result of such process or course of development; adaptive modification. The most exact synonym is *differentiation* (which see). It is common to say *differentiation* of structure, but *specialization* of function, giving to the former word a morphological and to the latter a physiological significance. Since, however, change of form almost always implies change in use of the parts thus modified in adaptation to different purposes, the two words come to the same thing in the end, and may be interchanged. The whole course of biological evolution is from the most general to some particular form and function, or from that which is simple, primitive, indifferent, and low in the scale of organization to that which is a complex of particulars and thus highly organized. Such *specialization* is expressed both in the structure of any of the higher animals and plants, regarded as wholes to be compared with other wholes, and in the structure of their several parts, organs, or tissues, compared with one another in the same animal or plant, and compared with the corresponding parts, organs, or tissues in different animals and plants. The actual ways in which or means by which *specialization* is known or supposed to be effected are among the broadest problems in biology. See biological matter under *evolution, Darwinism, selection, survival, variation, species, protoplasm, morphology, homology, analogy, heredity, environment*, and words of like bearing on the points in question.

All physiologists admit that the *specialization* of organs, inasmuch as they perform in this state their functions better, is an advantage to each being.

specie (spē'siē or -shē), *n.* [L. *specie*, abl. of *species*, kind, formerly much used in the phrase *in specie*, in kind, in ML. in coin: see *species*.] 1. As a Latin noun, used in the phrase *in specie*, (a) in kind.

So a lion is a perfect creature in himself, though it be less than that of a buffalo, or a rhinoceros. They differ

but *in specie*: either in the kind is absolute; both have their parts, and either the whole. B. Jonson, Discoveries.

You must pay him *in specie*, Madam; give him love for his wit.

Dryden, Mock Astrologer, v. 1.

Uneconomical application of punishment, though proper, perhaps, as well in *specie* as in degree.

Bentham, Intro. to Morals and Legislation, xvi, 54, note.

(b) In coin. See def. 2. Hence, as an English noun.—2. Coin; metallic money; a medium of exchange consisting of gold or silver (the precious metals) coined by sovereign authority in pieces of various standard weights and values, and of minor coins of copper, bronze, or some other cheap or base metal: often used attributively. The earliest coinage of specie is attributed to the Lydians, about the eighth century B. C. Previously, and long afterward in many countries, pieces of silver and gold (the latter only to a small extent) were passed by weight in payments, as lumps of silver are still in China. The use of specie as a measure of price is based upon the intrinsic value of the precious metals as commodities, which has diminished immensely since ancient times, but is comparatively stable for long periods under normal circumstances. In modern civilized communities specie or bullion is largely used by banks as a basis or security for circulating notes (bank-notes) representing it. In times of great financial disturbance this security sometimes becomes inadequate from depletion or through excessive issues of notes, and a general suspension of specie payments takes place, followed by great depreciation of the paper money. General suspensions of specie payments occurred in the United States in 1837, 1857, and 1861, the last, due to the civil war, continuing till 1879. Specie payments by British banks were suspended by law, in consequence of the French wars, from 1797 to 1823, but were actually resumed by the Bank of England in 1821. Similar interruptions of solvency have occurred in the other European countries, resulting in some in the substitution of depreciated paper money for specie in ordinary use and reckoning.—*Specie circular*, in U. S. hist., a circular issued by the Secretary of the Treasury in July, 1836, by direction of President Jackson, ordering United States agents to receive in future only gold and silver or Treasury certificates in payment for government lands.

species (spē'shēz), *n.*; pl. *species*. [In ME. *spece*, *spice*, *species*, kind, *spice* (see *spice*); in mod. E. directly from the L.; = F. *espèce*, *species* (*espèces*, coin), = Sp. An appearance or representation to the senses or the perceptive faculties; an image presented to the eye or the mind. According to the Roman Catholic doctrine of transubstantiation, the species, the outward and visible forms or the appearance of bread and wine in the eucharist, are accidents only of bread and wine severally, the substance no longer existing after consecration. See *intentional species*, below.

4. One of the kinds of things constituting a combined aggregate or a compound; a distinct

constituent part or element; an instrumental means: as, the *species* of a compound medicine. [Now rare in this medical sense, and obsolete or archaic in others.]

E. Phillips, New World of Words (ed. 1706).

5. In *biol.*, that which is specialized or differentiated recognizably from anything else of the same genus, family, or order; an individual which differs, or collectively those individuals which differ, specifically from all the other members of the genus, etc., and which do not differ from one another in size, shape, color, and so on, beyond the limits of (actual or assumed) individual variability, as those animals and plants which stand in the direct relation of parent and offspring, and perpetuate certain inherited characters intact or with that little modification which is due to conditions of environment. *Species* is thus practically, and for purposes of classification, the middle term between *genus* on the one hand and *individual* (or *specimen*) on the other; and only the latter can be said in strictness to have material existence, so that *species*, like *genus*, etc., is in this sense an abstract conception. It is also an assured fact in biology that no given stock or lineage breeds perfectly true in all its individuals; the line of descent is always marked by modification of characters (due to the interaction between heredity and environment); the whole tendency of such modification is toward further specialization, in the preservation of the more useful and the extinction of the less useful or the useless characters, and thus to the gradual acquirement, by insensible increments, of differences impressed upon a plastic organism from without—which is as much as to say that new *species* have always been in process of evolution, and still continue to be so developed. (See biological senses of *evolution*, *selection*, *survival*, and *variation*.) Such evolution has in fact been arrested at some point for every *species* once existent whose members have perished in time past: and of those specific forms whose adaptation to their environment has fitted them to survive till the present some are tending to perpetuation and some to extinction, but all are subject to incessant modification, for better or worse. (See *atavism*, *reversion*, 2, *retrograde*, a, 3, *degradation*, 7, 8, and *parasitism*, 2.) Such are the views taken by nearly all biologists of the present day, in direct opposition to the former opinion of a special creation, which proceeded upon the assumption that all *species* of animals and plants, such as we find them actually to be, came into existence by creative fiat at some one time, and have since been perpetuated with little if any modification. In consequence of the fact that the greatest as well as the least differences in organisms are of degree and not of kind, no rigorous and unexceptionable definition of *species* is possible in either the animal or the vegetable kingdom; and in the actual naming, characterizing, and classifying of *species* naturalists differ widely, some reducing to one or two *species* the same series of individuals which others describe as a dozen or twenty *species*. (See *lumper*, 3, *splitter*, 2.) This, however, is rather a nomenclatural than a doctrinal difference. The difficulty of deciding in many cases, and the impossibility of deciding in some, what degree of difference between given specimens shall be considered specific, and so formally named in the binomial system, have led to the introduction of several terms above and below the *species* (see *subgenus*, *subspecies*, *conspecies*, *variety*, *race*, 3, 5 (a) (b), *intergrade*, v. 1), and also to a modification of the binomial nomenclature (see *polynomial*, 2, and *trinomial*). Two tests are commonly applied to the discrimination between good *species* and mere *subspecies* or *varieties*: (1) the individuals of thoroughly distinct *species* do not interbreed, or, if they are near enough to hybridize, their progeny is usually infertile, so that the cross is not in perpetuity: the horse and ass offer a good case in point; (2) the specific distinctions do not vanish by insensible degrees when large series of specimens from different geographical localities or geological horizons are available for comparison; for, should characters assumed to be distinctive, and therefore specific, be found to grade away under such scrutiny, they are by that fact proved to be non-specific, and the specimens in question are reducible to the rank of *conspecies*, *subspecies*, *varieties*, or *Races*. Attempts which have been made to separate mankind into several *species* of the genus *Homo* fail according to both of the criteria above stated. To these may be added, in judging the validity of an alleged *species*, the third premise, that stable specific forms are evolved by or in the course of natural selection only: for all the countless stocks or breeds resulting from artificial selection, however methodically conducted, tend to revert when left to themselves, and also hybridize freely; they are not therefore in perpetuity except under cultivation, and are no *species* in a proper sense, though their actual differences may have become, under careful selection, far greater than those usually accounted specific or even generic. (See *dog*, *rose*.) Taking into account geological succession in time as well as geographical distribution in space, and proceeding upon accepted doctrines of the evolution of all forms of animal and vegetable life from antecedent forms, it is evident, first, that "*species*" is predicable only by means of the "missing links" in the chains of genetic relationships; for, were all organisms that have ever existed before our eyes in their actual evolutionary sequences, we should find no gap or break in the whole series; but, secondly, that development along numberless diverging lines of descent with modification has in fact resulted (through obliteration of the consecutive steps in the process) in the living fauna and flora of the globe, in respect of which not only specific, but generic, ordinal, and still broader distinctions are easily and certainly predicable. It does not appear that any animal or plant has always maintained what we now find its specific character to be; yet the persistence of some forms under no greater variation than that usually ac-

counted generic is established, as in the case of the genus *Lingula*, whose members have survived from the Silurian to the present epoch with only specific modification. In the animal kingdom probably about 250,000 species have been described, recorded, and formally named by a word following the name of the genus to which they are severally ascribed (see under *specific*); the actual number of species is doubtless much greater than this; some 200,000 species are insects (see *Insecta*), of which 80,000 or more belong to one order (see *Coleoptera*). These estimates are exclusive of merely nominal species. (See *synonym*.) The known species of flowering plants are summed up by Durand in his "Index Generum Phanerogamorum" as follows: dicotyledons, 78,200; monocotyledons, 19,600; gymnosperms, 2,420—in all, 100,220. This is the net result after extensive sifting. To this number large additions are to be expected from regions, as central Africa, still imperfectly or not at all explored. Of the number of cryptogams no reliable estimate can at present be given. The described species of fungi, judging from the eight volumes of Saccardo's work now published, are likely to number, before sifting, about 50,000. Abbreviated *sp.*, with plural *spp.*

9. In math.: (a) A letter in algebra denoting a quantity. [This meaning was borrowed by some early writers from the French of Viète, who derived it from a Latin translation of Diophantus, who uses εἶδος to mean a term of a polynomial in a particular power of the unknown quantity.] (b) A fundamental operation of arithmetic. See the four species, below.

Disjunct species, in logic. See *disjunct*.—Intelligible species. See *intentional species*.—Intentional species, a similitude or simulacrum of an outward thing; the vicarious object in perception and thought, according to the doctrine held and attributed to Aristotle by the medieval realists, beginning with Aquinas. Such species were divided into *sensible species* and *intelligible species*, which distinction and terminology, originating with Aquinas, were accepted by Scotus and others. The sensible species mediated between the outward object and the senses. They were metaphorically called *emanations*, but, being devoid of matter, are not to be confounded with the emanations of Democritus, from which they also differ in being related to other senses besides sight. So far as they belong to the outward thing they were called *impressed*, so far as they are perceived by the mind *expressed species*. From these sensible species the agent intellect, by an act of abstraction, was supposed to separate certain intelligible species, which the higher or patient intellect was able to perceive. These intelligible species so far as they belong to sense were called *impressed*, so far as they are perceived by the intellect *expressed species*. Species were further distinguished as *acquired*, *intused*, and *connatural*. The doctrine of intentional species was rejected by the nominalists, and exploded early in the seventeenth century, but not until the nineteenth was it generally acknowledged to be foreign to the opinion of Aristotle.

—Nascent species, in *biol.*, a species of animal or plant in the act, as it were, of being born or produced; an incipient species, whose characters are not yet established in the course of its development.—Sensible species. See *intentional species*.—Species anthelmintica, a mixture of equal parts of absinthium, fennel, camomile, and santonica. Species diuretica, a mixture of equal parts of roots of lovage, asparagus, fennel, parsley, and butcher's-broom.—Species laxantes. Same as *St. Germain tea* (which see, under *tea*).—Species pectorales. Same as *breast tea* (which see, under *tea*).—Species sudorifica. Same as *round tea* (which see, under *tea*).—Subaltern species, in logic, that which is both a species of some higher genus and a genus in respect of the species into which it is divided.—The four species, the four fundamental operations of arithmetic—addition, subtraction, multiplication, and division. This phrase, rare in English but common in German, seems to have been first so applied by the East Frisian mathematician Gemma in 1540. It was borrowed from logic, where since Petrus Hispanus four species of logical procedure are enumerated in all the old books. Thus, Wilson (1551) says: "There be four kinds of argumentes, a perfecte argument, an unperfecte argument, an inductione, an example"; and Blundeville (1599): "There be foure principall kindes or formes of argumentation, that is, a syllogisme, an induction, an enthymeme, and example."

species-cover (spē'shēz-kuv'ēr), *n.* The cover used in a herbarium to inclose and protect all the species-sheets of a single species. Such covers are usually made of folded sheets of light-weight brown paper, a little larger than the species-sheets.

species-monger (spē'shēz-mung'gēr), *n.* In *nat. hist.*: (a) One who occupies himself mainly or exclusively in naming and describing species, without inclination to study, or perhaps without ability to grasp, their significance as biological facts; a specialist in species, who cares little or nothing for broader generaliza-

tions. (b) One who is finical in drawing up specific diagnoses, or given to distinctions without a difference. [Cant in both senses.]

species-paper (spē'shēz-pā'pēr), *n.* Same as *species-sheet*.

species-sheet (spē'shēz-shēt), *n.* One of the sheets or pieces of paper upon which the individual specimens of a species in a herbarium are mounted for preservation and display. They are usually made of heavy stiff white paper, the standard size of which is, in the United States, 16½ × 11½ inches, weighing about 28 pounds to the ream. Only a single species is placed on a sheet, and its label is placed in the lower right-hand corner.

specific (spē-sif'ik), *a.* and *n.* [*<OF. spécifique, F. spécifique = Sp. específico = Pg. específico = It. specifico (cf. G. spezifisch), <ML. specificus, specific, particular, <L. species, kind, + -ficus, <facere, make.*] 1. *a.* 1. That is specified or defined; distinctly named, formulated, or determined; of a special kind or a definite tenor; determinate; explicit: as, a specific sum of money; a specific offer; specific obligations or duties; a specific aim or pursuit.

To be actuated by a desire for pleasure is to be actuated by a desire for some specific pleasure to be enjoyed by oneself. T. H. Green, *Prolegomena to Ethics*, § 282.

In addition to these broad differences, there are finer differences of specific quality within each sense.

J. Sully, *Outlines of Psychol.*, p. 115.

2. Pertaining to or accordant with what is specified or determined; relating to or regarding a definite subject; conformable to special occasion or requirement, prescribed terms, or known conditions; having a special use or application.

It was in every way stimulating and suggestive to have detected a specific bond of relationship in speech and in culture between such different peoples as the English and the Hindus. J. Fiske, *Evolutionist*, p. 109.

3. Of or pertaining to a species. (a) Pertaining to a logical species. (b) In *zool.* and *bot.*, of or pertaining to species or a species; constituting a species; peculiar to, characteristic of, or diagnostic of a species; designating or denominating a species; not generic or of wider application than to a species: as, specific characters; specific difference; a specific name. See *generic*, *subgeneric*, *conspecific*, *subspecific*.

4. Peculiar; special.

The style, like the style of Boiardo in poetry, of Botticelli in painting, is specific to Italy in the middle of the fifteenth century. J. A. Symonds, *Italy and Greece*, p. 251.

5. In law, having a certain or well-defined form or designation; observing a certain form; precise.—6. In *med.*, related to special infection, particularly syphilitic infection; produced by some distinct zymotic poison.—Specific cause, in *med.*, a cause which in operation will produce some special disease.—Specific centers, points or periods in the course of evolution at which an organism is supposed to become specifically differentiated from a common stock, having assumed or acquired its specific characters.—Specific characters, in *zool.* and *bot.*, the diagnostic marks of a species; differences, of whatever kind, which are peculiar to a species and serve to distinguish it from any other. The sum of such characters, or the total specific characteristics, are also spoken of as the specific character. Any one such mark or feature is a specific character.—Specific denial, in law, denial which itself rehearses what is denied, or which sufficiently specifies what particular part of the adversary's allegations are denied, as distinguished from a general denial of all his allegations.—Specific difference, in logic. See *difference*.—Specific disease, a disease produced by a special infection, as syphilis.—Specific duty, in a tariff, an impost of specified amount upon any object of a particular kind, or upon a specified quantity of a commodity, entered at a custom-house.—Specific gravity. Thus, in the name *Felis leo*, *leo* is the specific name, designating the lion as a member of the genus *Felis*, and as specifically different from *Felis tigris*, the tiger, *Felis catus*, the wildcat, etc. Also called *nomen specificum*, and formerly *nomen triviale* or *trivial name*. See *binomial*, 2, and *nomen*.—Specific performance, relief, resistance. See the nouns.—Specific rotatory power. See *rotatory*.—Syn. 1 and 2. Particular, etc. See *special*.

II. *n.* Something adapted or expected to produce a specific effect; that which is, or is supposed to be, capable of infallibly bringing about a desired result; especially, a remedy which cures, or tends to cure, a certain disease, whatever may be its manifestations, as mercury used as a remedy for syphilis.

The act of making specific, or the state of having a specific character; reference to or correlation with a species or kind; determination of species or specific relation.

F. H. Bradley, *Ethical Studies*, p. 68.

4. In patent law, the applicant's description of the manner of constructing and using his invention. It is required to be so explicit as to enable any person skilled in the art or science to make and use the same; and in the United States it forms part of the patent, which cannot therefore protect the inventor in anything not within the specification.

5. In civil law, the formation of a new property from materials belonging to another person. Specification exists where a person works up materials belonging to another into something which must be taken to be a new substance—for example, where whisky is made from corn. The effect is that the owner of the materials loses his property in them, and has only an action for the value of them against the person by whom they have been used. The doctrine originates in the civil law, but has been adopted by the common law, under the name of *confusion* and *accession*, at least where the person making the specification acts in good faith.—Accusative of specification. Same as *synecdochical accusative*. See *synecdochical*.—Charge and specifications. See *charge*.—Law of specification, in *Kantian philos.*, the logical principle that, however far the process of logical determination may be carried, it can always be carried further.—Principle of specification, in *Kantian philos.*: (a) The logical maxim that we should be careful to introduce into a hypothesis all the elements which the facts to be explained call for, or that *entium varietates non temere esse minuendas*, which is a counteracting maxim to Occam's razor. 5. *pl.* A pair of lenses set in a frame adjusted to the eyes, to correct or improve defective vision; also, sometimes, a similar frame with pieces of plain white or colored glass to protect the eyes from glare or dust: commonly called a pair of spectacles. The frame was in former times usually of horn or tortoise-shell, and afterward of

son's vision. Spectacles with colored lenses, as green, blue, neutral tint, or smoke-color, are used to protect the eyes from a glare of light. *Divided spectacles* have each lens composed of two parts of different foci neatly united, one part for observing distant objects, and the other for examining objects near the eye. Another kind, called *perspective spectacles*, are intended to allow the eyes considerable latitude of motion without fatigue. The lenses employed in this case are of either a meniscus or a concave convex form, the concave side being turned to the eye. Spectacles with glazed wings or frames partly filled with crepe or wire gauze are used to shield the eyes from dust, etc.

And even with this I lost fair England's view,
And bid mine eyes be packing with my heart,
And call'd them blind and dusky spectacles,
For losing ken of Albion's wished coast.

silver; it is now usually of steel or of gold. It is made up of the "bridge," "rims" (or frames of the lenses), "bows," and "sides" or "temples"; but the bows are now often omitted. The frame is so constructed and adjusted as to rest on the nose and ears and hold the lenses in the proper position. Spectacles which are supported on the nose only, by means of a spring, are commonly called *eye-glasses*. Spectacles with convex lenses are for the aged, or farsighted; and spectacles with concave lenses are for the near-sighted. In both cases the value of spectacles depends upon their being accurately adapted to the per-

Spectroscopes.

90° between them (fig. 3). For certain rays—for example, the yellow—there is no divergence while a spectrum is obtained, since the dispersion of the flint-glass prism in one direction is greater than that of the two crown-glass prisms in the opposite direction. Other forms of direct-vision spectroscopes have also been devised. In the *grating spectroscope*, or *diffraction spectroscope*, a diffraction-grating (a series of very fine parallel lines ruled on glass or speculum-metal) takes the place of the prism; and the parallel rays falling upon it are reflected, and form a series of diffraction-spectra (see *diffraction*, *grating*, 2, and *interference*, 5), which are called *normal spectra* (see *spectrum*, 3), since the dispersion of the rays is proportional to their wave-length. A prism is sometimes used before the telescope to separate parts of the successive spectra which would otherwise overlap. If a Rowland grating (see *diffraction*) is employed, the arrangements can be much simplified, since the large concave surface of the grating forms an image directly, which may be received upon a screen, or for study upon a photographic plate, or viewed through an eyepiece with cross-wires to fix the position of the lines observed. The grating is supported at one end of a rigid bar, in practice about 21 feet in length, at the other end of which, and at the center of curvature of the concave surface, is the eyepiece or support for the sensitive plate. The ends of this bar rest on carriages moving on two rails at right angles to each other; and, as the end carrying the eyepiece is moved, the whole length of the spectrum (several feet) may be successively observed, the fixed beam of parallel rays from the slit falling upon the grating as its position is slowly turned. The whole apparatus is mounted on rigid supports in a room from which all light but that received through the slit is carefully excluded. A high degree of dispersion is thus obtained, combined with the advantage of the normal spectrum, and the further advantages that the amount of light employed is large, while the disturbing effect of the absorption of the material of the prisms is avoided. See further under *spectrum*.—**Analyzing spectroscope**, **integrating spectroscope**, terms applied to the spectroscope (Young) to describe its use, with or without a lens throwing an image of the luminous object upon the slit. In the former case, different parts of the slit are illuminated by light from different parts of the object, and their spectra can be separately compared, or, in other words, the light is thus analyzed; while in the second case, when the collimator is pointed toward the source of light, the combined effect of the whole is obtained.—**Half-prism spectroscope**, a spectroscope in which the beam of rays enters the prism at right angles to one face, and suffers dispersion only on emerging from the face opposite and inclined to it. The half-prism ordinarily employed is half of a compound prism such as is used in the direct-vision spectroscope.—**Rainband-spectroscope**. See *rainband*.

spectrum (spek'trum), *n.*; pl. *spectra* (-trā). [*< NL. spectrum, a spectrum, < L. spectrum, an appearance, an image or apparition: see specter.*] 1. A specter; a ghostly phantom.—2. An image of something seen, continuing after the eyes are closed, covered, or turned away. If, for example, one looks intently with one eye upon any colored object, such as a wafer placed on a sheet of white paper, and immediately afterward turns the same eye to another part of the paper, one sees a similar spot, but of a different color. Thus, if the wafer is red, the seem-

ing spot will be green; if black, it will be changed into white. These images are also termed *ocular spectra*.

3. In physics, the continuous band of light (*visible spectrum*) showing the successive prismatic colors, or the isolated lines or bands of color, observed when the radiation from such a source as the sun, or an ignited vapor in a gas-flame, is viewed after having been passed through a prism (*prismatic spectrum*) or reflected from a diffraction-grating (*diffraction- or interference-spectrum*). The action of the prism (see *prism and refraction*) is to refract the light and at the same time to separate or disperse the rays of different wave-lengths, the refraction and dispersion being greater as the wave-length diminishes. The grating (see *grating*, 2), which consists usually of a series of fine parallel lines (say 10,000 or 20,000 to the inch) ruled on speculum-metal, diffracts and at the same time disperses the light-rays, forming a series of spectra whose lengths depend upon the fineness of the lines. If, now, a beam of white light is passed through a slit, and then by a collimator lens is thrown upon a prism, and the light from this received upon a screen, a colored band will be obtained passing by insensible degrees, from the less refrangible end, the red, to the more refrangible end, the violet, through a series of colors ordinarily described as red, orange, yellow, green, blue, indigo, and violet. A similar effect is obtained from a grating, with, however, this difference, that in the prismatic spectrum the red covers only a small part relatively of the colored band, since the action of the prism is to crowd together the less refrangible rays and separate the more refrangible rays of less wave-length, and thus distort the spectrum. The diffraction-spectrum, on the other hand, shows the red occupying about the same space as the blue and violet, and is called a *normal spectrum*. When the light from different sources is studied in the spectroscope, it is found, first, that a solid or a liquid when incandescent gives a continuous spectrum, and this is true of gases also at great pressures; second, bodies in the gaseous form give discontinuous spectra, consisting of colored bright lines (*line-spectrum*) or bands (*band-spectrum*), or of bands which under certain conditions appear as channelled spaces or flutings (*fluted spectrum*), and these lines or bands for a given substance have a definite position, and are hence characteristic of it; third, if light from an incandescent solid or liquid body passes through a gas (at a lower temperature than the incandescent body), the gas absorbs the same rays as those its own spectrum consists of; therefore, in this case, the result is a spectrum (*absorption-spectrum*) continuous, except as interrupted by black lines occupying the same position as the bright lines in the spectrum of the gas itself would occupy. An absorption-spectrum, showing more or less sharply defined dark bands, is also obtained when the light has passed through an appropriate liquid (as blood), or a solid such as a salt of didymium (see further under *absorption*). For example, the spectrum from a candle-flame is continuous, being due to the incandescent carbon particles suspended in the flame. If, however, the yellow flame produced when a little sodium is inserted in the non-luminous flame of a Bunsen burner is examined, a bright-yellow line is observed; if a red lithium flame, then a red and a yellow line are seen; the red strontium flame gives a more complex spectrum, consisting of a number of lines, chiefly in the red and yellow; and so of other similar substances. For substances like iron, and other metals not volatile except at very high temperatures, the heat of the voltaic arc is employed, and by this means their spectra, often consisting of a hundred or more lines (of iron at least 2,000), can be mapped out. Still again, if the light from the sun is studied in the same way, it is found to be a bright spectrum from red to violet, but crossed by a large number of dark lines called *Fraunhofer lines*, because, though earlier seen by Wollaston (1802), they were first mapped by Fraunhofer in 1814; this name is given especially to the more prominent of them, which he designated by the

Fixed Lines and Colored Spaces of Prismatic Spectrum (I) and Normal Spectrum (II).

1, red; 2, red-orange; 3, orange; 4, orange-yellow; 5, yellow; 6, green-yellow and yellow-green; 7, green and (7½) blue-green; 8, cyan-blue, blue and (10½) blue-violet; 9, violet; 10, violet; A, a, B, C, etc., Fraunhofer lines.

letters A to H, etc. (See the figures.) These lines, as explained above, are due to the absorption by gases, either in the sun's atmosphere or in that of the earth. When the light is passed through a train of prisms, or reflected from a Rowland grating, and thus a very high degree of dispersion obtained, the rays are more widely separated and the spectrum can be more minutely examined. Studied in this way, it is found that the dark lines in the solar spectrum number many thousands, the greater part of which can be identified in the spectra of known terrestrial substances. Thus, the presence in the sun's atmosphere of thirty-six elements has been established (Rowland, 1891); these include sodium, potassium, calcium, magnesium, iron, copper, cobalt, silver, lead, tin, zinc, titanium, aluminum, chromium, silicon, carbon, hydrogen, etc. The radiation from the sun consists not only of those rays whose wave-length is such as to produce the effect of vision upon the eye, but also of others of greater wave-length than the red rays and less wave-length than the violet; the spectrum from such a source consequently includes, besides the luminous part, an invisible part (*invisible spectrum*) below the red, called the *infra-red* region, and another beyond the violet, called the *ultra-*

violet. The first region is also present in the spectrum from any hot body, and the latter in that from a body at a high temperature—for example the incandescent carbons of an arc electric light. Thus, Langley by means of his bolometer has proved the existence of rays having a wave-length nearly twenty times that of the luminous red rays, in the radiation of the surface of the moon, and corresponding to a temperature not far from that of melting ice. Further, while the visible spectrum includes rays separated by only about one octave (since the wave-length for the extreme red is approximately twice that of the extreme violet), the full spectrum, from the extreme ultra-violet to the longest waves recognized by the bolometer, embraces more than seven octaves. In other words, it extends from rays having a wave-length of 0.18 of a micron to those whose wave-length is 30 microns (1 micron = 1000 millimeter). The invisible regions of the spectrum cannot be directly studied by the eye, but they can be explored, first by photography, it being possible to prepare suitable plates sensitive to the infra-red as well as others sensitive to ultra-violet rays, and such photographs show the presence of many additional absorption-lines. The invisible infra-red region (*heat-spectrum*) can also be explored by the thermopile and still better the bolometer, and the distribution of the heat thus examined, and a thermogram of the spectrum constructed in which the presence of "cold" absorption-bands is noted. Still again, the method of phosphorescence is employed to give a photograph of the spectrum, while fluorescence is made use of in studying the ultra-violet region. In studying the invisible heat-spectrum lenses and prisms of rock-salt must be used, because the dark rays of long wave-length are largely absorbed by glass; further, in investigating the invisible ultra-violet region quartz is similarly employed, since it is highly transparent to these short wave-length vibrations. In many investigations it is of great advantage to use the grating-spectroscope, especially one provided with a concave Rowland grating, since then the normal spectrum (fig. 11.) is obtained directly without the use of the usual lenses and prisms, and hence free from their absorbing effects. Recent photographs of the solar spectrum obtained by Prof. Rowland in this way give a clearness of definition combined with high dispersion never before approached. Thus, in their enlarged form as published (1890), the double sodium-lines are widely separated, and sixteen distinct fine lines may be counted between them. It was formerly the custom to divide the solar spectrum into three parts, formed by the invisible heat-rays, the luminous rays, and the so-called chemical or actinic rays. This threefold division of the spectrum is, however, largely erroneous, since all the rays of the spectrum are "heat-rays" if they are received upon an absorbing surface, as lamplack; and, while it is true that the chemical change upon which ordinary photography depends is most stimulated by the violet and ultra-violet rays, this is not true universally of all chemical changes produced by direct radiation. The rays from the lowest end of the spectrum to the highest differ intrinsically in wave-length only, and the difference of effect observed is due to the character of the surface upon which they fall. The spectra of the stars, of the comets, nebulae, etc., can be studied in the same way as the solar spectrum, and the result has been to throw much light upon the constitution of these bodies; the spectrum of the aurora has been similarly examined. In addition to its use in the study of cosmical physics, spectrum analysis has proved a most delicate and invaluable method to the chemist and physicist in the examination of the different elements and their compounds. By this method of research a number of new elements have been detected (as rubidium, cesium, indium, thallium); and recently the study of the absorption-spectra of the earth's—obtained from samarskite, gadolinite, and other related minerals—has served to show the existence of a group of closely related elements whose existence had not before been suspected. Further, the study of the change in the spectra of certain elements under different conditions of temperature has led Lockyer to some most important and suggestive hypotheses as to the relation between them and their possible compound nature.

By using new kinds of glass which allow of proportional dispersion in different parts of the spectrum (see *apochromatic*), Abbe has made lenses which collect three colors to one focus, leaving only a small residual aberration uncorrected, which is called the *tertiary spectrum*.

how to work him or wind him or govern him, proceedeth
from a heart that is double and cloven.
—*Bacon*, *Advancement of Learning*, i.

3. Given to speculation; contemplative; theo-
retical.
He [Washington] was not a *speculative*, but a practical
man; not at all devoted to Ideas.
—*Theodore Parker*, *Historic Americans*, Washington, p. 114.

Speculative men are deemed unsound and frivolous.
—*Emerson*, *Misc.*, p. 12.

4. Purely scientific; having knowledge as its
end; theoretical: opposed to *practical*; also
(limiting a noun denoting a person and signifying
his opinions or character), in theory, and not,
or not merely, in practice; also, cognitive; intel-
lectual. In this sense (which has no connection with
speculation), *speculative* translates Aristotle's *theōrētikos*.
Thus, *speculative science* is science pursued for its own
sake, without immediate reference to the needs of life, and
does not exclude experimental science.

I do not think there are so many *speculative* atheists
as men are wont to imagine.
—*Boyle*, *Christian Virtuoso*, part i.

It is evidently the intention of our Maker that man
should be an active and not merely a *speculative* being.
—*Reid*, *Active Powers*, Int.

When astronomy took the form of a *speculative* science,
words were invented to denote distinctly the conceptions
thus introduced.
—*Whewell*, *Philos. of Inductive Sciences*, I. liii.

A distinction merely *speculative* has no concern with
the most momentous of all practical controversies.
—*J. R. Seeley*, *Nat. Religion*, p. 51.

2. The pursuit of truth by means of thinking,
especially mathematical reasoning and logical
analysis; meditation; deep and thorough con-
sideration of a theoretical question. This use of
the word, though closely similar to the application of
speculatio in the Latin of Boethius to translate *θεωρία*, is
chiefly due to 1 Cor. xii. 12, "now we see through a glass,
darkly," where 'glass' is in the Vulgate *speculum*. But

some writers, as Milton and Cooper, associate the meaning
with *specula*, 'a watch-tower.'

For practise must agree with *speculation*,
Belief & knowledge must guide operation.
—*Times*, White (L. E. T. S.), p. 147.

Thenceforth to speculations high or deep
I turn'd my thoughts. —*Milton*, P. L., ix. 602.

scarcely sustain its own weight.
—*Darwin*, *Nature and the Bible*, p. 240.

—4. The investing of money at a risk of loss
on the chance of unusual gain; specifically,
buying and selling, not in the ordinary course
of commerce for the continuous marketing of
commodities, but to hold in the expectation of
selling at a profit upon a change in values or
market rates. Thus, if a merchant lays in for his regular
trade a much larger stock than he otherwise would
because he anticipates a rise in prices, this is not termed
speculation; but if he buys what he does not usually deal
in, not for the purpose of extending his business, but for
the chance of a sale of the particular articles at a profit by
reason of anticipated rise, it is so termed. In the language
of the exchanges, *speculation* includes all dealing in fu-
tures and options, whether purchases or sales.

The establishment of any new manufacture, of any new
branch of commerce, or of any new practice in agriculture,
is always a *speculation* from which the projector promises
himself extraordinary profits.

—*Adam Smith*, *Wealth of Nations*, I. x. 1.
A vast speculation had fail'd,
And ever he mutter'd and madden'd.
—*Tennyson*, *Maud*, i. 3.

5. A game at cards, the leading principle of
which is the purchase of an unknown card on
the calculation of its probable value, or of a
known card on the chance of no better appear-
ing during the game, a part of the pack not
being dealt. —*Latham*. = *Syn. 2. Hypothesis*, etc. See
theory.

The act of one who spells; the manner of forming words with letters; or thography. *Spellinge*, syllabiarior. *Prompt. Parc.*, p. 468. Our common *spelling* is often an untrustworthy guide to etymology. *J. Hadley, Essays*, p. 356. To prepare the way for such a change [a reform in spelling] the first step is to break down, by the combined influence of enlightened scholars and of practical educators, the immense and stubborn prejudice which regards the established modes of spelling almost as constituting the language, as having a sacred character, as in themselves preferable to others. All agitation and all definite proposals of reform are to be welcomed so far as they work in this direction. *Proc. Amer. Philol. Assoc.*, VII, 35. It may be observed that it is mainly among the class of half-taught dabbles in philology that etymological *spelling* has found its supporters. All true philologists and philological bodies have uniformly denounced it as a monstrous absurdity, both from a practical and a scientific point of view. *H. Sweet, Handbook of Phonetics*, p. 201. 2. A collocation of letters representing a word; a written word as spelled in a particular way. Our present spelling is in many particulars a far from trustworthy guide in etymology, and often, indeed, entirely falsifies history. Such *spellings* as island, author, delight, sovereign, require only to be mentioned, and there are hundreds of others involving equally gross blunders, many of which have actually corrupted the spoken language. *H. Sweet, Handbook of Phonetics*, p. 200. *Phonetic spelling.* See *phonetic*.—*Spelling reform*, the improvement by regulation and simplification of the conventional orthography of a language, specifically of the English language; the proposed simplification of English orthography. The spelling of all languages having a recorded history tends to lag behind the changes of pronunciation, and in time a reform becomes necessary. In English, since the gradual fixation of the spelling after the invention of printing, the separation of spelling and pronunciation has become very wide, and numerous proposals for spelling reform have been made. The present organized effort for spelling reform has arisen out of the spread of phonography, which is based on phonetic spelling, and from the more recent spread of the study of comparative philology, which is also based on phonetics. Proposals for a gradual reform in spelling have been put forth jointly by the American Philological Association and the Philological Society of England, and are advocated by the Spelling Reform Association. Amended spellings have been accepted to some extent by various periodicals, and are admitted, less freely, into recent books. Movements for spelling reform exist also in France, Germany, Denmark, and other countries. A spelling reform has been accomplished in Dutch, Spanish, and other tongues, and to some extent, by government action, in Germany. *spelling-bee* (*spel'ing-be*), *n.* Same as *spelling-match*. *spelling-book* (*spel'ing-būk*), *n.* A book from which children are taught to spell. *spelling-match* (*spel'ing-mach*), *n.* A contest for superiority in spelling between two or more persons or parties. tre, spelt; < LL. *spelta*, spelt.] A kind of wheat commonly known as *Triticum Spelta*, but believed to be a race of the common wheat, *Triticum sativum* (*T. vulgare*). Spelt is marked by the fragile rachis of the spike, which easily breaks up at the joints, and by the grains being adherent to the chaff. It was cultivated by the Swiss lake-dwellers, by the ancient Egyptians, and throughout the Roman empire, and is still grown in the colder mountainous regions of Europe and elsewhere. It makes a very fine flour, used especially for pastry-making, but the grain requires special machinery for grinding. *spelt² (*spelt*), *n.* [*< ME. spelt; a var. of spelt.*] A splinter, splint, or strip; a spell or spill. Like almost all the ancient and a considerable part of the modern philosophical systems, it is a philosophy of evolution; but it differs from most of these in reducing evolution to the rank of a mere secondary principle, and in making the immutable law of mechanics the sole fundamental one. Spencer has formally stated his philosophy in sixteen propositions, which concern the relations of evolution and dissolution. These are of a special and detailed character, so that he does not countenance the claim made for him of the principle of evolution itself. His sixteenth proposition states that under the sensible appearances which the universe presents to us, and "transcending human knowledge, is an unknown and unknowable power." *spencer-mast* (*spen'sēr-māst*), *n.* See *mast¹.*****

It is characterized by the presence of small scarious stipules, by flowers with five styles alternate with the five sepals, and by a one-celled capsule with its five valves opposite the sepals. There are 2 or 3 species, widely scattered through temperate regions of either hemisphere, and especially abundant in fields and cultivated places of the Old World. They are annual herbs with dichotomous or clustered branches, the swollen and succulent axils bearing apparent whorls of awl-shaped leaves. The small white or pink flowers form raceme-like cymes with conspicuous pedicels. The species are known by the general name of *spurry*, sometimes *sandweed*.

'whale's seed,' the substance having been regarded as the spawn of the whale; < L. *sperma*, seed, + *ceti*, gen. of *cetus*, < Gr. *κῆτος*, whale; see *Cet*.] 1. *n.* A peculiar fatty substance contained in the characteristic adipose tissue of the cavity of the head of the sperm-whale or cachalot, *Physeter* or *Catodon macrocephalus*, and related cetaceans. During the life of the animal the spermaceti is in a fluid state, and when the head is opened has the appearance of an oily white liquid. On exposure to the air the spermaceti concretes and precipitates from the oil, from which it may then be separated. After being purified by an elaborate process the spermaceti concretes into a white, crystallized, brittle, semi-transparent unctuous substance, nearly odorless and insipid. It dissolves in boiling alcohol, and as the solution cools it is deposited in perfectly pure lamellated crystals. In this state it is called *cetin*. Spermaceti is a mixture of various fatty acids and derivatives of the acids. It is bland and demulcent, but in medicine it is chiefly employed externally as an ingredient in ointments, cerates, and cosmetics. It has also been largely used in the manufacture of candles.

By this [fallacy of Equivocation] are they deluded who conceive *spermaceti* [*sperma Ceti*, Pseud. Ep. 1646], which is found about the head, to be the spawn of the whale.

There are about 175 species, scattered through tropical and subtropical regions, and particularly common in America. They are annual or perennial herbs or low undershrubs, with smooth, rough, or hairy stems, commonly with four-angled branchlets. They bear opposite leaves, which are either sessile or petioled, membranous or coriaceous, nerved or feather-veined. The stipules are united with the petioles into a bristle-bearing membrane or sheath. The small sessile flowers are solitary in the axils or variously clustered, often in dense axillary and terminal heads, and are white, pink, or blue. In allusion to the heads, the species are called *buttonwood*. Five species occur in the United States all southern and summer-flowering and with a short white corolla; *S. glabra*, the most common, extends into Ohio. Several species are in repute for medicinal properties, especially as substitutes for *ipocatantha*, for which *S. ferruginea* and *S. pauciflora* are used in Brazil, and *S. verticillata* in the West Indies. spermatophore (spér' mā-tō-fōr), *n.* [< Gr. σπέρμα(τ-), seed, + φέρω = E. bear¹.] A special case, capsule, or sheath containing spermatozoa; specifically, one of the peculiar spermatie cysts of cephalopods (also called *spermatie* or *seminal cartridge*, *seminal rope*, or *filament of Neddham*), usually forming a long cylindrical structure in which several envelopes may be distinguished. The contents of such a spermatophore are not exclusively seminal, for in the hinder part of each there is a special substance, the exploding mass, which serves to discharge the packet of spermatozoa. These are invested in a special tubular tunic, and packed in the front part of the spermatophore, like a charge of shot in a cartridge in front of the powder. Behind this packet of sperm the exploding mass forms a spiral coil, which extends through the greater part of the spermatophore and is continuous behind with the coat of the latter. When the spermatophore is wetted it swells up and bursts, through the force of the spring coiled inside, and the spermatozoa are discharged with considerable force. A spermatophore thus offers a striking analogy to the nematophore or thread-cell of a coelenterate, though the object attained is not urtication or netting, but a seminal emission and consequent impregnation of the female. A spermatophore of some sort, less complex than that of cephalopods, is very commonly found in several classes of invertebrates.

Spermatozooids of different species.

male; a spermatie cell or filament; a spermatozoan or spermatozoid. Spermatozoa are the vital and essential product of a spermary, male gonad, or testis, as ova are of the ovary or female gonad; their production, or the ability to produce them, is the characteristic distinction of the male from the female organism, whatever their size or shape or other physical character, and however various may be the organ in which they are produced. Spermatozoa, like ova, have the morphological value of the cell; and a spermatozoön is usually a cell in which a cell-wall, cell-contents, and cell-nucleus, with or without a nucleolus, may be distinguished. The form may be spherical, like the ovum, and indistinguishable therefrom by any physical character; more frequently, and especially in the higher animals, these little bodies are shaped like a tadpole, with a

male; a spermatie cell or filament; a spermatozoan or spermatozoid. Spermatozoa are the vital and essential product of a spermary, male gonad, or testis, as ova are of the ovary or female gonad; their production, or the ability to produce them, is the characteristic distinction of the male from the female organism, whatever their size or shape or other physical character, and however various may be the organ in which they are produced. Spermatozoa, like ova, have the morphological value of the cell; and a spermatozoön is usually a cell in which a cell-wall, cell-contents, and cell-nucleus, with or without a nucleolus, may be distinguished. The form may be spherical, like the ovum, and indistinguishable therefrom by any physical character; more frequently, and especially in the higher animals, these little bodies are shaped like a tadpole, with a

small spherical or discoidal head, a succeeding rod-like or bacillar part, and a long slender tail or caudal filament, capable of spontaneous vibratile movements, by means of which the spermatozoa swim actively in the seminal fluid, like a shoal of microscopic fishes, every one seeking, in the passages of the female into which the fluid has been injected, to discover the ovum in which to bury itself, in order to undergo dissolution in the substance of the ovum. They are smaller than the corresponding ovum, and several or many of them may be embedded in one ovum. The actual union of spermatozoa with an ovum, and fusion of their respective protoplasms, is required for impregnation, and is the consummation of sexual intercourse, to which all other acts and processes are simply ancillary or subservient. Spermatozoa may be killed by cold, or chemical or mechanical injury, like any other cells. These bodies, very similar to various animalcules, were discovered and named *spermatozoa* by Leewenhoeck in 1677; they were at first and long afterward regarded as independent organisms, variously classed as parasitic helminths or infusorians—such a view being held, for instance, by Von Baer so late as 1827 or 1835. Von Siebold, who found them in various vertebrates, called them *spermatozooids*. Their true nature appears to have been first recognized by Kolliker. Spermatozoa or their equivalents are diagnostic of the male sex under whatever conditions they exist, whether in male individuals separate from the female, or in those many hermaphrodite animals which unite the two sexes in one individual; and the organ which produces them is invariably a testis or its equivalent spermary, of whatever character. The male elements of the lowest animals, however, as *Protozoa*, do not ordinarily receive the name *spermatozoa*, this being specially applied to the more elaborate male cells of the character above described. The origination of spermatozoa has of late years been the subject of much research and discussion; the details of the process, as observed in different animals, or under different conditions of investigation, together with conflicting doctrinal conclusions, have occasioned a large special vocabulary. See many words preceding and following this one.

They have olive-brown, branching, filamentous fronds, with corticating cells wanting or confined to the base of the frond. The axis and branches are terminated by a large apical cell, from which, by transverse, longitudinal, and oblique divisions, a solid frond is formed whose external surface is composed of rectangular cells arranged in regular transverse bands. The unilocular and plurilocular sporangia are spherical or ellipsoidal, borne on short pedicels; reproduction is non-sexual, by means of propagula. It first appears on the shoots, leaves, and berries of grape-vines as minute brown spots which are a little depressed in the middle and have a slightly raised darker-colored rim. These spots soon increase in size and elongate longitudinally. On the fruit the spots retain a more or less regularly rounded outline, and have a well-defined band of bright vermilion between the dark border and the central portion. Finally, under the action of the disease, the berries dry up, leaving nothing, apparently, but the skin and seeds. Spheniscidæ (sfê-nis'i-de), *n. pl.* [NL., < *Spheniscus* + -idæ.] The penguins as a family of squamipennate or brevipennate palmiped natorial birds, of the order *Pygopodes*; the only family of *Spheniscomorpha*, *Squamipennes*, *Impennes*, or *Ptilopteri*, so strongly marked that it is regarded as representing a superfamily, order, or even superorder, though formerly included in the *Alcidæ*, or auk family. The wings are reduced to flippers, like a seal's or turtle's. They hang by the side, and cannot be closed like those of other birds; in swimming under water they are flapped alternately with a peculiar motion suggesting that of the blades of a screw propeller. They are covered with small scaly feathers in which no remiges can be distinguished, and their bones are peculiarly flat, and not hollow. The feet are four-toed and webbed, with very short broad tarsi, the bones of which are more separate than the metatarsals of any other birds. In walking or standing the whole tarsus rests on the ground, so that the birds are plantigrade; and in swimming under water the feet act mainly as rudders. The beak varies in form in different genera. The plumage is uniformly implanted in the skin, without any apteria; and there is a highly developed system of subcutaneous muscles, contributing to the sinuous movements of the birds under water, suggestive of those of the duck-mole. The feathers of the upper parts and wings are scaly, with thick, flattened shafts and slight webbing. The *Spheniscidæ* are confined to the southern hemisphere, and abound in cold temperate and antarctic waters, especially about the southern end of Africa and South America, where they live in communities, often of great extent. There are about 14 species, one of which reaches Brazil and another Peru. The generic forms are *Aptenodytes*, the king-penguins, of great size, with slender bill; *Pygoscelis*, a similar but long-tailed type; *Dasyrhamphus*, with extensively feathered bill; *Eudyptula*, of very small size; *Eudyptes* (or *Catarractes*), the rock-hoppers, which are crested, and hop instead of waddling; and *Spheniscus*, the jackass-penguins. There is a fossil penguin, *Palæodyptes antarcticus*, from the Tertiary of the west coast of Nelson Island, which was a giant, 6 or 7 feet tall. *Aptenodytidae* is a synonym. See the generic names, *Spheniscomorpha*, and cuts under *Eudyptes*, *metatarsus*, *penguin*, *Pygoscelis*, *Spheniscus*, and *Squamipennes*.

It is the hemihedral form of the square pyramid of the tetragonal system.—2. *n.* In *anatomy*, a large and important compound bone of the skull; so called from its shape and connections in man.

The sphenoid bone is a large, complex bone of the skull. It is a wedge-shaped bone, and its shape is often compared to a butterfly. It is located in the middle of the skull, between the frontal bone and the occipital bone. It has a central body, and from this body, several processes extend outwards. These processes are the sphenoidal processes, which are the sphenoidal process of the frontal bone, the sphenoidal process of the parietal bone, the sphenoidal process of the temporal bone, and the sphenoidal process of the occipital bone. The sphenoid bone is also the site of the sphenoidal foramen, which is the opening through which the sphenoidal nerve passes.

It has a solid median and inferior body, and bears on each side two pairs of wings, greater and lesser, separated by the sphenoidal fissure from each other. It is a collection of bones, not a single bone, its composition including: in man and the mammals generally, (a) a basisphenoid, the principal posterior part of the body of the bone, bearing (b) the alisphenoids, the pair of greater wings, these elements forming with the parietal bones the second or parietal segment of the cranium; (c) the presphenoid, the lesser anterior moiety of the body of the bone, bearing (d) the orbitosphenoids, the pair of lesser wings, or processes of Ingrassias, these forming with the frontal bones the third or frontal cranial segment; (e) a pair of pterygoid bones, the so-called internal pterygoid processes; (f) a pair of spongy bones, the sphenoturbinates. The development of the human sphenoid is from 14 centers of ossification, 8 in the postsphenoid division, and 6 in the presphenoid division. Below mammals, in *Sauropsida* (birds and reptiles), the sphenoid is simplified by subtraction of the pterygoids, which then form permanently distinct bones, and complicated by the addition of other elements, especially an underlying membrane-bone called the *parasphenoid*. In *Ichthyopsida* (amphibians and fishes) further and very great modifications occur. To the sphenoid of man are attached twelve pairs of muscles.

In geom., a solid figure generated by the revolution of a semicircle about its diameter. This is substantially Euclid's definition. The modern definition is a quadric surface having contact with the absolute throughout a conic, and therefore everywhere equidistant from a center. 5. One of the supposed concentric and eccentric revolving rigid and transparent shells called crystalline, in which, according to the old astronomers (following Eudoxus), the stars, sun, moon, and planets were severally set, and by which they were carried in such a manner as to produce their apparent motions. The term is now generally restricted to the sphere of the fixed stars, and is recognized as a convenient fiction. It is also loosely applied to the planets themselves.

In *geom.*, a solid generated by the revolution of an ellipse about one of its axes. When the generating ellipse revolves about its longer or major axis, the spheroid is *prolate* or *oblong*; when about its less or minor axis, the spheroid is *oblate*. The earth is an oblate spheroid—that is, flattened at the poles, so that its polar diameter is shorter than its equatorial diameter. (See *earth*, 1.) The same figure is assumed by the other planets; hence the properties of the oblate spheroid are of great importance in geodesy and astronomy.—**Universal spheroid**, a surface generated by the revolution of an ellipse about any diameter.

Spheroidal epithelium. See *epithelium*. **Spheroidal state or condition**, the condition of water or other liquid when, on being placed on a highly heated surface, as red-hot metal, it assumes the form of a more or less flattened spheroid, and evaporates without ebullition.

The spheroid in this condition does not touch the surface of the metal but floats on a layer of its own vapor, and evaporates rapidly from its exposed surface. It is heated mainly by radiation from the hot surface, since the layer of intervening vapor conducts heat very feebly. The formation of a layer of non-conducting vapor explains why it is possible to dip the wetted hand into molten iron with impunity. It is sometimes spoken of as the *caloric* or *caloric point*.

spheroidally (sfer'oid-ál-i), *adv.* In a spheroidal manner; so as to form a spheroid or spheroids.

Perhaps the most remarkable spheromeres are those two which, in the Venus's-girdle, give that ctenophore a ribbon-like figure by their enormous development. See cut under *Cestum*.

spherometer (sfer'oid-ál-mēr), *n.* [**< Gr. σφαῖρα**, a ball, sphere, + **μέτρον**, measure.] An instrument for measuring the radii of spheres; a sphere-measurer. It is of especial service to opticians in determining the focal lengths, etc., of lenses. The common form (see figure) consists of a vertical screw *c*, with a large graduated head *a*, turning in a socket supported by three legs whose hard steel points are exactly equidistant. The fixed scale *b* at the side, together with the graduated screw-head, makes it possible to measure with great accuracy the distance between the extremity of the screw and the plane passing through the ends of the three supports, when, for example, all the points are in contact with the surface of the sphere. If, in addition, the distance between the ends of the supports is known, a simple calculation gives the radius of the sphere. The same instrument may also be used to determine with precision the thickness of a plate, as (in the figure) *A*, placed upon a horizontal surface.

Same as *orbicularis oris* (which see, under *orbicularis*).—**Sphincter ani**, the sphincter of the anus, under which name two distinct muscles are known. (a) The sphincter ani proper, sphincter externus, or external sphincter is a thin, flat plane of voluntary muscular fibers supplied by hemorrhoidal branches of nerves from the sacral plexus, surrounding the anus, subcutaneous and intimately adherent to the integument, of elliptical form 3 or 4 inches in long diameter, and an inch wide across. It arises from the tip of the coccyx, and is inserted into the tendinous raphe of the perineum. Like most sphincters, it consists of symmetrical lateral halves united by a raphe in front of and behind the opening it incloses. (b) The sphincter recti, sphincter internus, or internal sphincter surrounds the lower end of the rectum, forming a muscular ring about an inch in extent and a quarter of an inch thick, and consists of an aggregation and thickening of the circular fibers of the gut. This sphincter is involuntary, and in health maintains its tonic contractility, which yields by reflex action to the pressure of the contents of the bowel.—**Sphincter oculi**, or **sphincter palpebrarum**, the orbicular muscle of the eyelids, which surrounds and closes them. Usually called *orbicularis palpebrarum*. See cut under *muscle*.—**Sphincter oris**, the oral sphincter. Also called *sphincter pupillæ* and *sphincter iridis*.—**Sphincter pylori**. See *pylorus*.—**Sphincter recti**, the internal sphincter ani (see above).—**Sphincter vaginae**, an elliptical muscle surrounding the orifice of the vagina, corresponding to the bulbocavernosus of the male. Also called *constrictor vaginae*.—**Sphincter vesicae**, the unstriated involuntary muscular fibers around the neck of the urinary bladder.—**Sphincter vesicae externus**, the partly plain partly striated muscular fibers which surround the prostatic part of the urethra. Sphingidae (sfín'jī-dē), *n. pl.* [NL. (Leach, 1819), < *Sphinx* (*Sphing-*) + *-idae*.] An important family of heterocerous lepidopterous insects, with fusiform antennae, typified by the genus *Sphinx*, including all those commonly known as sphinxes, sphinx-moths, hawk-moths, or humming-bird moths. The body is robust; the abdomen is stout, conical, often tufted; the tongue is usually long and strong; the antennae have a hook at the tip; the wings are comparatively small and narrow, the fore wings acute at the tip. They are diurnal or crepuscular in habit, a few flying in the hottest sunshine, but the majority in the twilight. The larvae are large, naked, usually green in color, and generally furnished with a prominent caudal horn, which is sometimes replaced after the last molt by a shining lenticular tubercle. When full-grown they either pupate above ground, between leaves, in a slight cocoon, or more generally go deep under ground, and transform in an earthen cell. The long-tongued species have a special free and characteristic tongue-case. The species of temperate regions are divided into four principal subfamilies: *Macroglossinae*, *Chorocampinae*, *Sphinginae*, and *Smerinthinae*. From America north of Mexico 83 species have been described, about 50 from Europe, and rather more than 600 for the entire world. It is closely related to *Syntheres*; but the latter is more spiny, and has a broad, highly arched frontal region. The two genera are united by Brandt under the name *Cercolabes*. Each has several Neotropical species in Central and South America, east of the Andes, from southeastern Mexico and the West Indies to Paraguay.

sphinx (sfings), *n.*; *pl. sphinxes, sphinges* (sfing'sez, sfín'jēz). [= *F. sphinx* = *Sp. esfinge* = *Pg. esfinge* = *It. sfinge* = *G. sphinx*, < *L. sphinx*, < Gr. σφίγξ (*σφίγγ-*), *Eolie* σφίξ, a sphinx (Theban or Egyptian: see defs. 1 and 2); supposed to mean lit. 'strangler,' the story being that the Sphinx strangled those who could not solve her riddles; < σφίγ-

γιν, throttle, strangle, orig. bind, compress, fix; prob. = *L. figere*, fix (see *fix*); by some connected with *L. fascis*, a bundle: see *fascis*.] 1. [*cap.* or *t. c.*] In *Gr. myth.*, a female monster, said to have proposed a riddle to the Theban who passed her as she sat on a rock by the roadside, and to have killed all who were not able to guess it. The riddle, according to tradition, inquired what being has successively four, two, and three feet, and is weakest when it has most feet. Oedipus answered, Man, who creeps in infancy, afterward goes erect, and finally walks with a staff (a third foot). The Sphinx, in compliance with her own conditions, thereupon threw herself from her rock and died. In art this monster is represented with the body of a lion or a dog, winged, and the head and often the breasts of a woman.

For valour, is not Love a Hercules? . . .
Subtle as *Sphinx*. *Shaks.*, *L. L. L.*, iv. 3. 342.

In the third [court] . . . are two *Sphinges* very curiously carved in brass.

2. In *Egypt. antiq.*, a figure somewhat similar in composition to the Greek, having the body of a lion (never winged), and a male human head or an animal head. The human-headed figures have been called *androsphinxes*; those with the head of a ram, *criosphinxes*; and those with the head of a hawk, *hieracosphinxes*. Egyptian sphinxes are symbolical figures, having no connection with the Greek fable; and the Greeks probably applied the term *sphinx* to the Egyptian statues merely on account of the accidental external resemblance between them and their own conception. The Egyptian sphinxes were commonly placed in avenues leading to temples or tombs. The most celebrated example is the Great Sphinx near the great pyramids of Ghizeh, hewn out of solid granite, with the recumbent body of a lion, 146 feet long from the shoulders to the rump, and 56 feet high, and a man's head 28½ feet high from chin to crown. A small temple stood between the forepaws of this sphinx. There are also Oriental sphinxes, in general akin to the Egyptian, but more often winged than wingless. See cut under *androsphinx*.

3. In *her.*, a creature with a lion's body and a woman's head, but not necessarily like any ancient original. It is assumed to be winged; when not winged, it should be blazoned "sans wings."—4. An enigmatic or sphinx-like person; one who talks puzzlingly, or is inscrutable in disposition or character; one whom it is hard to understand.—5. In *entom.*: (a) A hawk-moth; a member of the genus *Sphinx* or the family *Sphingidae*. See cuts under *hawk-moth*, *hog-caterpillar*, *Lepidoptera*, and *Phidampelus*. (b) [*cap.*] [NL. (Linnaeus, 1767).] The typical genus of the family *Sphingidae*. At first it was co-extensive with this family; later it formed a group of variable extent; now it is confined to forms having the head small, the eyes lashed, tibia spinose, and fore tarsi usually armed with long spines. It is a wide-spread genus; 19 species occur in America north of Mexico. The larvae of this, as well as of other groups of the family *Sphingidae*, have the habit of erecting the head and anterior segments, from which Linnaeus derived a fanciful resemblance to the Egyptian Sphinx (whence the name).

6. The Guinea baboon, *Cynocephalus papio* or *Papio sphinx*. Also called *sphinx-baboon*.—*Abbot's sphinx*, *Thyreus abboti*, a small North American

A chenopodiaceous garden vegetable of the genus *Spinacia*, producing thick succulent leaves, which, when boiled and seasoned, form a pleasant and wholesome, though not highly flavored dish. There is commonly said to be but a single species, *S. oleracea*; but *S. glabra*, usually regarded as a variety, is now recognized as distinct, while there are two other wild species. The leaves of *S. oleracea* are sagittate, undivided, and prickly; those of *S. glabra* are larger, rounded at the base, and smooth. These are respectively the prickly-leaved and round-leaved spinach. There are several cultivated varieties of each one of which, with wrinkled leaves like a Savoy cabbage, is the Savoy or lettuce-leaved spinach. All these species are Asiatic; the cultivated plant was first introduced into Europe by the Arabs by way of Spain.

In man the bones composing the spinal column are normally thirty-three—seven cervical, twelve dorsal or thoracic, five lumbar, five sacral, and four coccygeal. These form a flexuous and

Human Spinal Column.

A, side view; B, same, in median sagittal section; C, front view; d, seven cervical; e, twelve dorsal; f, five lumbar; g, five sacral, fused in a sacrum; h, four caudal or coccygeals, forming a coccyx.

flexible column capable of bending, as a whole, in every direction. It is most movable in the lumbar and cervical regions, less so in the dorsal and coccygeal, fixed in the

sacral. Twenty-four of its bones are individually movable. The total length averages 26 or 27 inches. See *vertebra*, and cut under *backbone*.—**Spinal cord**, the main neural axis of every vertebrate, exclusive of the brain; the myelon, or the neuron without the encephalon; the spinal marrow, or nervous cord which extends in the spinal canal from the brain for a varying distance in different animals, and gives off the series of spinal nerves in pairs. The cord is directly continuous with the brain in

Cross-section of Human Spinal Cord.

comparable to the collic of the brain; but it generally solidifies, and also becomes fluted, or presents several parallel columns, from between certain of which the spinal nerves emerge. In man the cord is solid and subcylindrical, and extends in the spinal canal from the foramen magnum, where it is continuous with the oblongata, to the first or second lumbar vertebra. It gives off the spinal nerves, and may be regarded as made up of a series of segments, from each of which springs a pair of nerves; it is divided into cervical, thoracic, lumbar, sacral, and coccygeal regions, corresponding to the nerves and not to the adjacent vertebrae. There is an enlargement where the nerves from the arms come in (the cervical enlargement), and one where those from the legs come in (the lumbar enlargement). A cross-section of the cord exhibits a central H-shaped column of gray substance incased in white. (See figure.) The tracts of different functions are exhibited on one side of the cut; they are not distinguished in the adult healthy cord, but differ from one another in certain periods of early development, and may be marked out by secondary degenerations. The cord is a center for certain reflex actions, and a collection of pathways to and from the brain. The reflex centers have been located as follows: scapular, 5 C. to 1 Th.; epigastric, 4 Th. to 7 Th.; abdominal, 8 Th. to 1 L.; cremasteric, 1 L. to 3 L.; patellar, 2 L. to 4 L.; cystic and sexual, 2 L. to 4 L.; rectal, 4 L. to 5 L.; gluteal, 4 L. to 5 L.; Achilles tendon, 5 L. to 1 S.; plantar, 1 S. to 3 S. See also cuts under *brain*, *cell*, *Petromyzontidae*, and *Pharyngobranchii*.—**Spinal epilepsy**, muscle-clonus, spontaneous or due to assuming some ordinary position of the legs, the result of increased myotatic irritability, as in spastic paralysis.—**Spinal foramina**, the intervertebral foramina.—**Spinal ganglia.** See *ganglion*.—**Spinal marrow.** Same as *spinal cord*. **Spinal muscles**, the muscles proper of the spinal column, which lie longitudinally along the vertebrae, especially the epaxial muscles of the back, constituting what are known in human anatomy as the *third, fourth, and fifth layers* of muscles of the back (the so-called first and second "layers" of human anatomy being not axial, but appendicular). One of these is called *spinalis*.—**Spinal nerves**, the numerous pairs of nerves which arise from the spinal cord and emerge from the intervertebral foramina. In the higher vertebrates spinal nerves originate by two roots from opposite sides of that section of the spinal cord to which they respectively pertain—a posterior, sensory, or ganglionated root, and an anterior, motor, or non-ganglionated root, which usually unite in one sensorimotor trunk before emergence from the intervertebral foramina, and then as a rule divide into two main trunks, one epaxial and the other hypaxial. The number of spinal nerves varies within wide limits, and bears no fixed relation to the length of the spinal cord, which latter may end high in the dorsal region, yet give off a leash of nerves (see *cauda equina*, under *cauda*) which emerge from successive intervertebral foramina as far as the coccygeal region. The spinal nerves form numerous and intricate connections with the nerves of the ganglionic system. Their epaxial trunks are always few and small in comparison with the size, number, and extent of the ramifications of the hypaxial trunks, which latter usually supply all the appendicular and most of the axial parts of the body.—**Spinal reflexes.** See *reflex*.—**Spinal veins**, the numerous veins and venous plexuses in and on the spinal column, carrying off blood from the bones and included structures. In man these veins are grouped and named in four sets. See *vena*.

Sp. *espina* = Pg. *espinha* = It. *spina*, < L. *spina*, a thorn, prickle, also the backbone; prob. for **spicna*, and akin to *spica*, a point, spike: see *spike*.] In the sense of 'backbone' *spine* is directly < L. *spina*. Hence *spinach*, *spinage*, *spinal*, *spiny*, *spinet*, *spinney*, etc.] 1. In

bot., a stiff sharp-pointed process, containing more or less woody tissue, and originating in the degeneracy or modification of some organ. Usually it is a branch or the termination of a stem or branch, indurated, leafless, and attenuated to a point, as in the hawthorn, sloe, pear, and honey-locust; its nature is clearly manifest by the axillary position, and also by the fact that it sometimes produces imperfect leaves and buds. A spine may also consist of a modified leaf (all gradations being found between merely spiny-toothed leaves and leaves which are completely contracted into simple or multiple spines, as in the barberry), or of a persistent petiole, as in some *Astragali* and in *Fouquieria*, or of a modified stipule, as in the common locust. A spine is to be clearly distinguished from a prickle, which is merely a superficial outgrowth from the bark. See *prickle*, l. 1.

2. The backbone; the rachis, *spina*, or spinal column of a vertebrate. The name is due to the series of spinous processes of the several vertebrae which it presents, forming a ridge along the middle of the back. See *spinal column* (under *spinal*), and *vertebra*, *vertebral*.

3. A name of some part in various animals. (a) In *anat.*, a sharp process, point, or crest of bone; a spinous process, generally stouter than a styloid process: as, the spine of the ilium, of the ischium, of the scapula, of the pubis. See cuts under *innominatum* and *shoulder-blade*. (b) In *morph.*, a bony element, or pair of bony elements, which completes a segment of either the neural canal or the hemal canal of a vertebrate on the midline of the dorsal or ventral aspect of the body, the ossification intervening dorsad between a pair of neuropophyses or ventrad between a pair of hemapophyses, the former being a *neural spine*, the latter a *hemal spine*. Thus, the spinous process of a dorsal vertebra is the neural spine of that vertebra, and the segment of the sternum with which the rib of that vertebra articulates is the hemal spine of the same vertebra. Owen. See cuts under *dorsal*, *carapace*, and *endoskeleton*. (c) In *mammal.*, a modified hair; a sharp, stiff, hard, horny dermal outgrowth, as one of the quills of a porcupine, or of the prickles of the hedgehog or spiny anteater. In many animals the transition from soft fur through harsh or bristly pelage to spines is very gradual. See cuts under *Echinidae*, *Erinaceus*, and *porcupine*. (d) In *ornith.*, a spur or calcar, as of the wing or foot; a mucro, as of a feather. See cuts under *Palamedea*, *Rasores*, and *mucronate*. (e) In *herpet.*, a sharp, prickly scale of considerable size; a horn. See cuts under *Cerastes* and *Phrynosoma*. (f) In *conch.*, any considerable sharp projection of the shell. Such spines are endlessly modified in size, shape, and site. Good examples are figured under *nautilus*, *scorpion-shell*, and *Spondylus*. (g) In *Crustacea*, any considerable spinous process of the carapace, of the legs, etc. Such spines are the rule with most crustaceans. The large tail-spine of some is specified as the *telson*. (h) In *entom.*, any comparatively short sharp projection of the chitinous body-wall of an insect. Such occur commonly upon the larvæ of *Lepidoptera*, upon the bodies of many adult *Coleoptera*, *Hemiptera*, and *Hymenoptera*, and upon the legs (principally upon the tibiae) of these and nearly all *Orthoptera* and many *Neuroptera*. The body-spines of adult insects are always of great use in classification. (i) In *ichth.*: (1) A fin-spine: one of the unjointed and unbranched sharp bony rays of the fins, such as those

a, b, c, spines followed by soft rays of the dorsal, ventral, and anal fins of an acanthopterygian fish. a, ten spines; b, one spine; c, three spines.

a, b, c, spines followed by soft rays of the dorsal, ventral, and anal fins of an acanthopterygian fish. a, ten spines; b, one spine; c, three spines. (j) In *echinoderm.*, one of the movable processes which beset the exterior, as of an echinus, and are articulated with the tubercles of the body-wall. *Primary spines* are the large ones forming continuous series along the ambulacra, as distinguished from less-developed *secondary* and *tertiary* spines. Other spines are specified as *seminal*. See cuts under *Cidaris*, *Echinometra*, *Echinus*, *semida*, and *Spatangus*. (k) In general, some or any hard sharp process, like a spine; a thorn; a prickle; as, the *spine* at the end of the tail of the lion or the fer-de-lance.

4. In *mach.*, any longitudinal ridge; a fin. E. H. Knight.—5. In *lace-making*, a raised projection from the cordonnet: one of the varieties of pinwork; especially, one of many small points that project outward from the edge of the lace, forming a sort of fringe.—6. spinode (spi'nód), *n.* [*< L. spina*, a thorn, spine, + *nodus*, a knot.] In geom., a stationary point or cusp on a curve. A spinode may be conceived as resulting from the vanishing of the angle at a node between the two branches, the length of arc between them being reduced to zero, just as an inflection may be regarded as resulting from the vanishing of the interval between the two points of tangency of a bitangent, the total curvature between them at the same time vanishing. But this view in the latter case includes all the points of the inflectional tangent as points of the curve, and in the former case includes all lines through the spinode as tangents. For this reason the spinode, like the inflection, is reckoned as a distinct kind of singularity. A curve cannot, while remaining real, change continuously from having a cusp to having an acnode without passing through a form in which it has a spinode.

spinode-curve (spi'nód-kérv), *n.* A singularity of a surface consisting in a locus of points where tangent-planes to the curve intersect it in curves having spinodes at those points. The spinode-curve on a real surface is the boundary between a synclastic and an anticlastic region. It bears no resem-

blance to that singularity of a surface termed the *cuspidal curve*.

Spinozism (spi-nó'zizm), *n.* [*< Spinoza* (see *def.*) + -ism.] The metaphysical doctrine of Baruch (afterward Benedict) de Spinoza (1632–1677), a Spanish Jew, born at Amsterdam. Spinoza's chief work, the "Ethics," is an exposition of the idea of the absolute, with a monistic theory of the correspondence between mind and matter, and applications to the philosophy of living. It is an excessively abstruse doctrine, much misunderstood, and too complicated for brief exposition. The style of the book, an imitation of Euclid's "Elements," is calculated to repel the mathematician and logician, and to carry the attention of the ordinary reader away from the real meaning, while conveying a completely false notion of the mode of thinking. Yet, while the form is pseudomathematical, the thought itself is truly mathematical. The main principle is, indeed, an anticipation in a generalized form of the modern geometrical conception of the absolute, especially as this appears in the hyperbolic geometry, where the point and plane manifolds have a correspondence similar to that between Spinoza's worlds of extension and thought. Spinoza is described as a pantheist; he identifies God and Nature, but does not mean by Nature what is ordinarily meant. Some sayings of Spinoza are frequently quoted in literature. One of these is *omnis determinatio est negatio*, "all specification involves exclusion"; another is that matters must be considered *sub specie eternitatis*, "under their essential aspects."

 of America is *S. tristis*, etc. The name wavers in application,
 and is more or less inexactly synonymous with several

2. In *zool.*, an aperture, orifice, or vent through
 which air, vapor, or water passes in the act of
 respiration; a breathing-hole; a spiraculum: ap-
 plied to many different formations. Specifically —

 side) for each of the three thoracic segments, and for each
 of the anterior eight abdominal segments; but they are
 almost always lacking on some one or more of these. They
 are either simple openings into the respiratory system, or
 are provided with valves, sieves, or fringes of hair for the
 exclusion of foreign particles. See cut under *Systæchus*.

Spiræa (spi-rē'ā), *n.* [NL. (Tournefort, 1700),
 < *L. spiræa*, < *Gr. σπείραια*, meadow-sweet, so
 called from the shape of its follicles, < *σπείρα*,
 a coil, spire: see *spire*².] 1. A genus of ros-
 aceous plants, type of the *Spirææ*. It is charac-
 terized by fruit commonly of five follicles, contain-
 ing usually numerous linear seeds with a membranous
 or rarely coriaceous outer seed-coat and little or no
 albumen. The flowers have four or five calyx-lobes, as
 many rounded petals, twenty to sixty filiform stamens,
 and a smooth or woolly fleshy disk. The Himalayan
S. parvifolia is an exception in its solitary seeds and
 obconical calyx. There are about 50 species, widely
 scattered through temperate and cold regions of the
 northern hemisphere, and occurring rarely on mountains
 alternate the tropics. They are herbs or shrubs, bearing
 alternate simple pinnate or ternately compound leaves,
 usually furnished with free or wing-like and united stip-
 ules. The small white, pink, or rose-colored flowers form a
 copious axillary or terminal inflorescence, which is either
 a raceme, cyme, panicle, or corymb, or consists, as in *S.*
Aruncus, of a diffuse panicle composed of numerous elon-
 gated slender spikes. Most of the species are highly orna-
 mental in flower. They are now most commonly known,
 especially in cultivation, by the generic name *Spiræa*.
 Eleven species are natives of Europe, 3 of which occur in
 England; of these *S. Filipendula* is the dropwort, and the
 others, *S. salicifolia* and *S. Ulnaria*, are known as *meadow-*
sweet (the latter also as *queen-of-the-meadows*, which see).
 Six species are natives of the northeastern United States,
 of which *S. salicifolia* is the most widely distributed, a
 shrub with slender ascending spire-like
 branches, popularly
 known in the west as
steepbush, in America
 usually with white
 flowers, in Europe, Si-
 beria, Mongolia, and
 Japan, pink or rose-
 colored. It is often
 cultivated, especially in
 Russia, where a great
 many varieties have
 originated; in Wales it
 forms a large part of
 the hedges. For *S. to-*
mentosa, a similar pink-
 flowered eastern spe-
 cies, see *hardhack*; its
 representative on the
 Pacific coast, *S. Dou-*
glasii, with handsome
 whitened leaves, is one
 of the most showy of
 American shrubs. For
S. lobata, see *queen-*
of-the-prairie, and for *S.*
Aruncus, *goat's-beard*;
 the latter is one of the
 most ornamental plants
 of eastern woodland
 borders. For *S. hyper-*
cifolia, common in cul-
 tivation from Europe
 and Siberia, and also
 called *Italian may* and
St. Peter's wreath, see
bridal-wreath. Several
 species from Japan are
 now abundant in orna-
 mental grounds, as *S. Japonica* and its variety *S. For-*
tunei, and *S. prunifolia*, the plum-leaved spiræa, a white-
 flowered shrub with handsome silky leaves. *S. Thun-*
bergii from Japan is much used in parks, forming a
 small diffuse shrub 2 or 3 feet high with light recurving
 branches whitened before the leaves with a profusion of
 small flowers usually in threes in the axils. Some Asiatic
 species with pinnate leaves and large terminal panicles
 of white flowers are arborescent, as *S. sorbifolia*, often
 seen as a shrub in New England dooryards, and *S. Kan-*
chatica, with the panicles very large, the flowers fragrant
 and feathery. The former *S. opulifolia*, the ninebark, and
 its variety *aurea*, the golden spiræa of gardens, are now
 referred to *Neillia*, or by some separated as a genus *Physo-*
carpus. Many species possess moderate astringent or
 tonic properties; the roots of the British species are so
 used, and the flowers of *S. hypericifolia*; *S. Ulnaria* is
 valuable also as a diuretic. *S. tomentosa*, the principal
 American medicinal species, a plant of bitter and astringent
 taste, is used in New England and also formerly by
 the Indians as a tonic.

Spirææ (spi-rē'ē-ē), *n. pl.* [NL. (Bentham and
 Hooker, 1865), < *Spiræa* + *-æ*.] A tribe of poly-
 petalous plants, of the order *Rosaceæ*. It is char-
 acterized by flowers with bractless and commonly peris-
 tent calyx-lobes, ten or more stamens, from one to eight
 superior carpels, usually each with two or more pendulous
 ovules, either indehiscent or ripening into follicles, and
 not included within the calyx-tube. It consists of 10
 genera, of which *Spiræa* is the type. They are usually
 shrubs, all natives of the northern hemisphere; *Spiræa*
 only is of wide distribution; 4 others are confined to North
 America, of which *Nerissa* is found only in Alabama, and

 confined to Japan and China.

2. In *conch.*, all the whorls of a spiral univalve above the aperture or the body-whorl, taken together as forming a turret. In most cases the spire is exerted from the last turn of the shell, giving the ordinary turreted conical or beehive form of numerous gastropods; and in some long slender forms of many turns and with small aperture, the spire makes most of the length of the shell, as is figured at *Perithauma*, *Cerithium*, and *Peristoma* for example. In other cases, however, the spire scarcely protrudes from the body-whorl, and it may be even entirely included or contained in the latter, so that a depression or other formation occupies the usual position of the apex of the shell. (Compare *Conus*, *Urosalpinx*, *Capitulum*, *Caudofoveata* and *Urosalpinx*.) See also *conch. murex*.

They are rigid and furnished at each end with a cilium, and multiply by transverse division, the parts soon separating from one another. spirit (spir'it), *n.* [*< ME. spirit, spirite, spyrite, spirite* (also *spirit, sprite*, *> E. spritel*), *< OF. esprit, esperit, esprit, F. esprit* = *Sp. spiritu* = *Pg. espirito* = *It. spirito*, spirit (= *G. Cf. *spirite*, a doublet of *spirit*.] 1. According to old and primitive modes of thought, an invisible corporeal thing of an airy nature, scarcely material, the principle of life, mediating between soul and body. The primitive and natural notion of life was that it consisted of the breath, and in most languages words etymologically signifying 'breath' are used to mean the principle of life. *Spirit* is one of these, and translates the Greek πνεύμα. The ordinary notion of the Greek philosophers was that the soul is warm air. This was strengthened by the discovery, about the time of Aristotle (who, however, does not share the opinion), of the distinction between the veins and the arteries. It is found elaborately developed in the writings of the Stoics, and especially of Galen. The spirit in the body exists in various degrees of fineness. The coarser kinds confer only vegetative life, and betray themselves in eruptions, etc.; there are, besides, a vital spirit (*πνεύμα ζωτικόν*) and an animal or psychical spirit (*πνεύμα ψυχικόν*). At birth man was said to possess only vegetative spirit, but as soon as he draws breath this was thought to be carried through the left ventricle and the arteries to every part of the body, becoming triturated, and conveying animal life to the whole. The spirits were also said to be in different states of tension or tone, causing greater or less energy of body and mind. The vital spirits, being carried to the ventricles of the brain, were there further refined, and converted into spirits of sense, or animal spirits. In vision these spirits dart out from the eye to the object, though this be the most distant star, and immediately return laden in some form with information. This doctrine, modified by the addition of an incorporeal soul, and confused with the Hebrew conception of a spirit, was generally believed down to and into the scientific era. Old writers, therefore, who use phrases which are still employed metaphorically must be understood as meaning them literally. See *def. 3*.

There is no malice in this burning coal;
The breath of heaven hath blown his spirit out.
Shak., K. John, iv. 1. 110.

From the kind heat which in the heart doth reign
The spirits of life do their beginning take;
These spirits of life, ascending to the brain,
When they come there the spirits of sense do make.

These spirits of sense in fantasie's high court
Judge of the formes of objects ill or well;
And so they send a good or ill report
Down to the heart, where all affections dwell.

Besides, another motive power doth rise
Out of the heart, from whose pure blood do spring
The vital spirits, which, borne in arteries,
Continuall motion to all parts do bring.

Sir J. Davies, Nosce Teipsum.

Adam, now enforced to close his eyes,
Sunk down, and all his spirits became entranced.

Milton, P. L., xi. 419.

Thus much cannot be denied, that our soul acteth not immediately only upon bones, flesh, brains, and other such like gross parts of the body, but, first and chiefly, upon the animal *spirts*, as the immediate instruments of sense and fancy, as that by whose vigour and activity the other heavy and unwieldy bulk of the body is so nimbly moved. And therefore we know no reason why we may not assent here to that of Porphyrius: that the blood is the food and nourishment of the *spirts*, and that this *spirts* is the vehicle of the soul, or the more immediate seat of life.

Cudworth, Intellectual System, v. § 3.

2. The principle of life conceived as a fragment of the divine essence breathed into man by God. This conception is developed in the Old and New Testaments, in the writings of the Neoplatonists, and by theologians. In Biblical and theological language the spirit is the highest part of human nature, as most akin to the divine, connected mediately with the body through the soul, and spoken of alone, or in contradistinction to the body, or as distinguished from both body and soul (see *soul*).

All flesh died that moved upon the earth, . . . all in whose nostrils was the breath of the spirit of life.
Gen. vii. 21, 22.

The spirit of Elijah doth rest on Elisha. *2 Ki. ii. 15.*
My spirit is consumed, my days are extinct, the grave is ready for me. *Job xvii. 1.*

Who among men knoweth the things of a man, save the spirit of the man, which is in him? *1 Cor. ii. 11 (R. V.).*

Our body shall be turned into ashes, and our spirit shall vanish as the soft air. *Wisdom of Solomon, ii. 3.*

3. Metaphorically, animation; vivacity; exuberance of life; cheerfulness; courage; mettle; temper; humor; mood: usually in the plural. But in old writers this meaning is not figurative, since they conceived this quality to be due to the tension of animal spirits.

So feble were his *spirites*, and so low.
Chaucer, C. T., l. 1361.

Hastings went to the council that morning in remarkably high *spirits*. *J. Gairdner, Rich. III., ii.*

All furnish'd, all in arms; . . .
As full of spirit as the month of May.

I wonder you can have such *spirits* under so many distresses. *Sheridan, School for Scandal, iv. 1.*

4. A peculiar animating and inspiring principle; dominant influence; genius; that which pervades and tempers the conduct and thought of men, either singly or (especially) in bodies, and characterizes them or their works.

And by the general reverence God is praised.

Emerson, Compensation.

And that law of force which governs all the changes of character in a given people at a given time, which we call the Spirit of the Age, this also changes, though more slowly still.

W. K. Clifford, Lectures, I. 80.

5. The essence, real meaning, or intent of any statement, command, or contract: opposed to letter.

W. Wallace, Epicureanism, p. 171.

6. Incorporeal, immaterial being or principle; personality, or a personality, unconnected or only associated with a body: in Biblical use applied to God, and specifically [*cap.*] to the third person of the Trinity (the Holy Spirit); also to supernatural good and evil beings (angels).

God is a spirit: and they that worship him must worship him in spirit and in truth. *John iv. 24.*

But God hath revealed them unto us by his Spirit: for the Spirit searcheth all things, yea, the deep things of God. *1 Cor. ii. 10.*

Putting together the ideas of thinking and willing, or the power of moving or quieting corporeal motion, joined to substance, of which we have no distinct idea, we have the idea of an immaterial spirit.

Locke, Human Understanding, II. xxiii. 15.

If we seclude space out of our consideration, there will remain but two sorts of substances in the world: that is, matter and mind; or, as we otherwise call them, body and spirit.

2. [*l. c.*] A member of this genus.

 tualism originated in the State of New York in the year 1848,
 and since that time has extended over the United States
 and Europe. The mediums through whom the supposed
 communications take place are of various kinds, no fewer than
 twenty-four different classes being mentioned in the books
 explanatory of spiritualism. Among the chief methods of
 communication are rappings, table-tippings, writing, and

 dium is supposed to be fully possessed by the spirit for
 the time being. Spiritualism has no formal system of
 theology, and it is contended by many of its advocates that
 it is not necessarily inconsistent with the maintenance
 of a faith otherwise Christian, and that spirit-communica-

Some of the most valuable strains of domestic animals and cultivated plants have arisen thus spontaneously. (b) The tendency to purposeless activity of the muscular system of animals, whereby they execute movements independent of external stimulus.

Such actions, though voluntary, lack recognizable motive, and appear to depend upon the tension of a vigorous nervous system refreshed by repose. Such spontaneity is notable in the great activity of children and the gambols of young animals.—**Spontaneity of certain cognitive faculties**, in the philosophy of Kant, the self-activity of those faculties which are not determined to act by anything in the sense-impressions on which they act. But the conception is not made very clear by Kant.

spontaneous (spŏn-tā'nē-us), *a.* [*= F. spontané = Sp. Pg. espontáneo = It. spontaneo, < LL. spontaneus, willing, < L. sponte(t)-s, will, only in gen. spontis and abl. sponte, of one's own will, of one's own accord.*] 1. Proceeding from a conscious or unconscious internal impulse; occurring or done without the intervention of external causes; in a restricted sense, springing from one's own desire or volition, apart from any external suggestion or incitement. Of late the employment of *spontaneous* in the sense of 'irrelative' or 'not controlled by a definite purpose' is creeping in from the French; but this is an objectionable use of the term.

The *spontaneous* grace with which these homely duties seemed to bloom out of her character.

4. In *biol.*, instinctive or automatic, as some actions of animals which depend upon no external stimulus and are performed without apparent motive or purpose; uninfluenced by external conditions, as a change in structural character. Compare *spontaneity*, 2. Spontaneous actions may be either voluntary, in a usual sense, as the gambols of puppies or kittens, or involuntary and quite uncontrollable by the will. Of the latter class, some are abnormal, as spontaneous (in distinction from induced) somnambulism, and these are also called *idiopathic*.—**Center of spontaneous rotation**. See *rotation*.—**Spontaneous axis**, an axis of rotation of a body under instantaneous forces, in case there is no translation in the first instant.—**Spontaneous cause**, a cause that is moved to causing by the end or the object.—**Spontaneous combustion**. See *dislocation*, 2(a).—**Spontaneous energy**, free energy, unrepressed and unforced.—**Spontaneous evolution**, in *obstet.*, the spontaneous expulsion of the fetus in a case of shoulder presentation, the body being delivered before the head.—**Spontaneous generation**. See *generation* and *abiogenesis*.—**Spontaneous suggestion**, suggestion by the action of the laws of association, without the intervention of the will.—**Syn. 1. Willing**, etc. (see *voluntary*), instinctive, unbidden.

In bot., a single cell which becomes free and is capable of developing directly into a new morphologically and physiologically independent individual. The name is given to all the reproductive bodies of cryptogamous plants, which are the analogues of the seeds of the higher or flowering plants, from which they further differ by having no embryo. In the majority of cases a spore consists of a nucleated mass of protoplasm, inclosing starch or oil as reserve nutritive material, surrounded by a cell-wall. In those cases in which the spore is capable of germination immediately on the completion of its development, the cell wall is a single delicate membrane consisting of cellulose; but in those cases in which the spore must pass through a period of quiescence before germination, the wall is thick and may consist of two layers, an inner, the endospore, which is delicate and consists of cellulose, and an outer, the exospore, which is thick and rigid, frequently dark-colored, and beset externally with spines or bosses, and which consists of cutin. In certain plants, as some algae and fungi, spores are produced which are for a time destitute of any cell-wall. They are further peculiar in that they are motile, on which account they are called *zoospores*. In the various divisions of cryptogams the spores are produced in many different ways and under various conditions. See *acidospore*, *ascospore*, *bispore*, *carpospore*, *chlamydospore*, *clinospore*, *macrospore*, *microspore*, *ouspore*, *protospore*, *pseudospore*, *pycnidiospore*, *stylaspore*, *teleutospore*, *tetraspore*, *uredospore*, *zoospore*, *zygospore*, etc.

In biol., an organic body of extremely minute size, and not subject to ordinary classification; a sporozoid or zoospore; a living germ, as a seed of certain diseases.—4. Figuratively, a germ; a seed; a source of being.

[*< NL. < Gr. σπορίον, σπόρος*, seed (see *spore*²), + *dim. -ιδιον*.] In bot.: (a) A name restricted by some to the reproductive organs or so-called spores which are borne upon and detached from a promycelium; by others also given to the spores produced in asci or ascospores. (b) A spore. See *promycelium*.

Sporobolus (spôr-rob'ö-lus), *n.* [NL. (R. Brown, 1810), so called with ref. to the seed, which is loose and readily scattered; < *Gr. σπόρα*, σπόρος, seed, + *βάλλειν*, cast forth.] A genus of grasses, of the tribe *Agrostideæ*, type of the subtribe *Sporoboleæ*. It is characterized by a diffuse or cylindrical and spike-like panicle, generally containing very numerous and small one-flowered spikelets, each with three awnless glumes, the flowering glume equal to the others or shorter, and the grain free and often readily deciduous from the glumes and palea. In typical species the pericarp, unlike that of most grasses, is a utricle; other species having the usual caryopsis are sometimes separated as a genus *Vilfa* (Beauvois, 1812). There are about 80 species, widely scattered through temperate and warmer regions, numerous in America, but with only one species, *S. pungens*, in Europe. They are commonly perennials, slender or sometimes coarse, the leaves flat or rolled, the panicle various, sometimes inclosed in the leaf-sheaths, the spikelets sometimes minute. They are known in general as *droopseed-grass*, some as *rush-grass* (which see).

The fructification developed from an archicarp or procarp in *Fungi* and *Rhodophyceæ* is a sporocarp; such also is the sporogonium in *Muscinææ*. The term is also used for the capsule-like structure formed by the indusium inclosing the sporangia in the heterosporous *Filicineæ*. Goebel. See cuts under *annulus*, *Marsilea*, *mildev*, and *moss*.

The fronds are cylindrical or tubular, branching, and composed within of elongated cuboidal cells, which become smaller and roundish at the surface; the fructification is in external scattered sori. The order contains 4 or 5 genera and about 25 species.
